CLINICAL LECTURES

ON THE PRACTICE OF PHYSIC,

DELIVERED IN THE
THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D., EDIN.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c.

LECTURE XI.

ON THE MORBID CONDITIONS OF THE LUNGS, ETC., CONTINUED.

GENTLEMEN,—Inflammation, whether it attack one or other portion of the respiratory system, must always be viewed in a serious light; for even when only affecting the first passages, such as the nostrils, it is very apt, if neglected, to be propagated downwards, and terminate in more vital parts. An acute inflammation of the nostrils usually proceeds from retained excretions, or atmospheric poisons, and is the first and most obvious symptom of a common cold, or nasal catarrh, and more especially of influenza. It is characterized by redness, dryness, heat, and swelling, and a concurrent febrile excitement. The patient is unable to draw air through the passages; and at length there is augmented discharge, at first of mucus, and afterwards it may be of pus and blood. It may be treated by leeching, though that is seldom resorted to, inasmuch as the vessels, if much gorged, usually relieve themselves by a spontaneous hæmorrhage. Most generally it is met by such medicines as will open the various emunctories, and procure vent for the "*peccant humours*." Strong saline purgation is one very efficacious remedy. If hæmorrhage proceed too far, it may be stopped either by plugging, or by snuffing up a little of the acetate of lead; and if a chronic inflammatory action be continued, after the subsidence of the acute attack, giving rise to a constant flow of muco-purulent matter, a similar snuffing up of calomel will be most likely to arrest so disagreeable a symptom. But INFLAMMATION OF THE LARYNX is one of the most formidable diseases that can assail the human frame, especially on account of its tendency to induce suffocation. It may arise from the application of some external irritant, or from poison

circulating in the blood; or may take place in the course of severe pneumonia, or bronchitis. Its marked characteristics are,—pain, and a sense of intense especial heat in the part, even while the rest of the body is of very exalted temperature, difficulty of swallowing, difficulty of speech, and intensely laboured and harsh respiration. This latter symptom is the most obvious one to any bystander, and the most painful and alarming to the patient himself. At first, of course, these sensations are comparatively slight, but, as the disease runs on, they become dreadful in the extreme, and exhibit all that you might expect from a protracted suffocation. Even though mercury, antimony, and abstraction of blood, be resorted to at the beginning, the affection will too often run its course in spite of all efforts, and terminate fatally within a very short time, exhibiting after death a red and thickened indurated condition of all the tissues of the larynx, and its aperture narrowed to a mere slit. In the young woman Perkins, who came in with continued fever, and whose chief local inflammation lay in the chest, we had an instance of this disease. The fever, pneumonia, and bronchitis had already been gradually subdued, when, being a little light-headed, and believing she was quite well, she walked into the stone passage, and stood there for a time. Shortly after she complained of sore-throat, when, fearing what might be the result, two re-lays of leeches were applied, and she was placed under mercury and antimony, with a nitrate of silver gargle. In spite of these efforts the inflammation increased, the respiration became hissing, and then harsh, the lips and cheeks became blue, the pulse rose to 140, the *ala nasi* were expanded, and the greatest anxiety was depicted in the brow and eyes. At length, as you will see, on referring to the case, matters came to such an extremity, that Mr. Moore thought of performing tracheotomy; before doing so he sent to ask my consent, but meanwhile the poor girl had died. This was the more annoying as it was the only instance during eighteen months in which we had lost a case of fever here, the death occurring, too, just on the verge of convalescence. In like manner, with numerous young children, though the symptoms may be temporarily subdued, yet they are apt to return with renewed force, and too often terminate fatally, in spite of all efforts. I have said that the treatment must consist of local abstraction of blood, with mercury and antimony, in frequently repeated doses, and the warm bath. Tracheotomy should also

be kept in view, but, as in private practice, there is frequently such a prejudice against this proceeding, as to deter the attendant from resorting to it, or even suggesting it; so in hospitals it is very seldom had recourse to, except until too late. Both physicians and surgeons seem generally to feel that they are not called upon to use such a remedy until all others have proved of no avail. They are liable to consider that while, on the one hand, any certainty of recovery after the operation is very problematical, the probability of death, on the other hand, is pretty strong, and therefore shrink from the responsibility of the death being imputed to the operation, rather than the disease. But it should be recollected that it is the delay of the operation that gives the victim so little chance of benefit from it. It should also be borne in mind that it is only done with the view of allowing the patient to have breath, while the other remedies are exerting their influence on the larynx; and that, even though it should fail as an expedient of cure, it is very likely to operate so far as to procure a comparatively easy death. All this makes me inclined to be an advocate for the timely performance of tracheotomy in this disease, and, in the next case that occurs in the hospital, I shall certainly resort to it at an earlier period than heretofore; and, indeed, the house-surgeon has my authority for its performance without waiting for my presence.

The slow chronic inflammation and thickening of the laryngeal textures which are apt to occur in certain strumous and syphilitic habits, giving rise to loss of voice, great hoarseness, and some slight sense of pain, accompanied with the presence of something that can never be hawked up, is an equally formidable disease, with the last and not less fatal, though not so sudden and startling. The morbid appearances after death are, a great thickening of all the tissues, including those of the vocal chords. The surface has the appearance of the skin of the hand, softened, thickened, and puckered, by long steeping in hot water, covered with a thick glairy mucus, and here and there a patch of inflammation, or congestion. The accurate pathological theory of such local appearances I do not profess at all to understand. That there is a degenerate hypertrophy is obvious, but why this seat should be specially chosen for the deposit, is quite another question; I cannot answer it, and shall, therefore, only state facts. It is almost always accompanied with a very large or universal deposit of tubercle in the lungs, and those who are seized with it seldom or never recover. Good examples have been exhibited of this morbid condition in the cases of Claridge and Dremer. Both of them died mere skeletons, with their lungs riddled throughout, yet Dremer declared himself to the last as getting well fast. Greig furnishes us, on the other hand, with an instance of its partial arrest. In each of these cases the remedies for phthisis were employed, but, in addition, local leeching was also resorted to, and an inhalation used, composed of conium and iodine, which seemed to produce very beneficial effects. In the two fatal cases the feelings of uneasiness were relieved, and in that of Greig the voice was restored, and the pain on swallowing, &c., quite

dispersed. He left the hospital tolerably well, but I have not heard of him since. Some good has also been effected by the application of strong solutions of the nitrate of silver; but, upon the whole, I can speak most favourably of the iodine and conium as giving relief almost invariably. This, as you may be aware, was the favourite remedial application of Sir Charles Scudamore in almost all respiratory cases whatever. Such narrow views of pathology are altogether untenable, yet each favourite remedy, like this, may be found highly useful for its own specific purpose, that of this one being to allay irritation and promote absorption.

IN INFLAMMATION OF THE TRACHEA, OR CROUP, we have a specimen of one more very formidable disease, chiefly attacking young persons. It is most commonly traceable to some exposure to cold during raw and damp weather, or in cold moist situations. Sometimes it is preceded by all the characteristics of a simple cold, with rough cough, hoarseness, and some amount of fever; but the true and alarming symptoms of fibrinous croup are generally rather sudden in their manifestation, and either appear rather unexpectedly, after some continuance of the above condition, or all at once with scarcely any premonitory symptoms whatever, so that—as observed by a vigorous describer of disease, the mother of a family may be suddenly startled from her sleep, by that terrible clanging cough which is so peculiar to croup, and which bodes so ominously of a quick and fatal issue. The essence of the disease consists in the exudation of fibrinous lymph from the inflamed surface of the trachea, so solid and tenacious, that it is firmly moulded to all the irregularities of the organ, adhering to it like a true membrane, and becoming thicker and thicker as the morbid action advances. Many beautiful specimens are to be seen of this fibrinous coating after it has been thrown off, when it exhibits itself as an exact mould of the trachea, as if taken in pliable wax. This, you know, is rather an exceptional event in mucous surfaces, unless inflammation run exceedingly high indeed, and its frequent occurrence in this situation is doubtless due, partly to the intense action going on, and partly to some peculiarity in the natural organization of the part. Almost invariably, in such situations, it is pus, and not fibrinous lymph, that is thrown out. But for this law the most disastrous consequences might frequently happen from inflammatory attacks of the nostrils, the œsophagus, the rectum, the urethra, &c., leading to the blocking up of such passages. As it is, it is singular enough how such an event should so much more often occur in so essential an organ as the trachea than anywhere else, but such is the fact, and it must make us view the affection in a very serious light.

The great object in such a case must be to abate the hyperæmia and to evacuate the existing obstructions to respiration. The first is to be attained by abstraction of blood, and the administration of such remedies as may lessen the force of the circulation, as antimony and digitalis, though both are to be avoided if the powers of life be very low. A few leeches along the track of the windpipe, and a quarter of a grain of antimony every

hour, will soon take some effect on the constitutional action, and by the addition of mercury, the natural secretions will be promoted, the tenacious exudations rendered more fluid, and also absorbed. If the false membranes are inclined to be loosened from their attachments to the mucous surface, their expulsion will be much promoted in a mechanical way by the exhibition of emetics; but, upon the whole, the greatest sources of confidence must be in abstraction of blood, and the speedy influence of antimony and mercury, the latter being applied by friction as well as by the mouth. Tracheotomy does not, in this instance, hold out such hopes as in laryngitis, because we can scarcely tell how far the inflammation has proceeded, and therefore even after making an opening at the lowest point, we may find it of no use.

From the peculiarities connected with the local inflammations already described, it was necessary to treat of them individually; but, for the remaining portions of the respiratory apparatus, I shall reduce them synthetically to one head of hyperæmia, instead of dividing them into bronchitis, pneumonia, &c. ACUTE HYPERÆMIA may attack either the mucous membrane of the bronchi and bronchilli, with their sub-tissues, in which event it is considered BRONCHITIS, or it may seize on the vesicular portions of the lungs, in which case it is called PNEUMONIA. Both, however, are to be viewed as the same action, differing only in extent of surface and certain distinctive effects referable to certain differences as to function and structure. Thus, the bronchi being merely air passages, their diseased condition is of less importance than that of the vesicles, within which the proper function of the respiration is carried on. The bronchi are also more apt to be affected on both sides equally than the vesicles; and from their greater openness they are more likely to throw out simply protective mucus or expectorable pus, than that fibrinous lymph, which is too often the result of vesicular inflammation. The ordinary causes of this inflammation, like those in other internal organs, are the application of external irritants, or revulsed excretions, or febrile and other poisons circulating in the blood. When the bronchi alone are affected, there will necessarily be, according to the extent or severity of the action, more or less cough, and more or less impeded respiration. The cough will at first be dry, as the immediate consequence of all inflammation is a stoppage of the natural secretions; but, in due time, if not checked at the first onset, there will follow first an expectoration of mucus, more or less tenacious, which will afterwards become muco-purulent, or entirely purulent, according to circumstances. When the membranes have become so thickened by the exudations of inflammation, or so obstructed by the superficial discharges, some difficulty of breathing will be experienced. This, arising from a physical cause, will be so far permanent and equal; but as some nervous irritation must arise under the presence of such foreign matter, this difficulty of breathing will be liable to rather sudden fits of increase, due to occasional asthmatic constriction. A chronic inflammation therefore, of the bronchitic kind, usually gives rise to

habitual asthma, and also thereby induces emphysema. In the first stage of bronchial inflammation, there will be heard, from the dryness of the membrane, a harsh hissing sound under respiration, over the course of the larger tubes, while the vesicular murmur may be unaltered, and this will be accompanied with dry cough, and some sense of rawness down the centre of the chest. As exudations make their appearance, those sounds will become rough, and more complicated with others, arising from the air bubbles traversing the effused fluids, and bursting therein. This stage will now be marked by a moister cough, accompanied with an expectoration, the more thin the more easy, and the more tenacious the more painful. While, therefore, these proofs of bronchial inflammation may be gathered from the stethoscope, the general expansion of the chest may be pretty good, and the vesicular murmur soft and regular. The sounds on percussion may also be universally good; though, sometimes, when a pellet of hardened mucus may have blocked up one or more of the air passages, there may be a good sound over the obstructed portion of lung; but yet no proper expansion and no vesicular murmur. So far, a simple bronchitis is easily diagnosticated, but it must be recollected that the question is too often complicated with previously-existing disease, such as solidification of the lung from tubercle or plastic lymph, or the exudation of serum, or pus, or lymph from pleurisy, or the presence of a tumour; or an obliteration of the lung altogether. Under such circumstances, it becomes extremely difficult to form any decided opinion; unless you are already master of the previous history of the patient, in which case it were comparatively easy to know whether any such solidification were of old standing or not, and what was its real nature. The various solidifications that may occur are often not to be distinguished from one another except by such history and other collateral evidence. Fluid effusions cannot be discovered by succussion when the cavity is perfectly full of any homogenous mass. The chief proof, therefore, is the absence of the vocal thrill, and as to whether the fluid be serum or pus, or an admixture of both, that is only to be known by the preceding symptoms, or by the trocar. An obliteration of the lung is of course still more difficult to be proved. The nature of such difficulties may be instanced in certain actual cases treated within the hospital. Thus, in the case of the boy Green, the clay-like dulness of the right side was referred to tubercle from collateral evidence alone, inasmuch as he was pale and emaciated, and had had degenerative disease in the knee-joint, &c.; yet it is not impossible that it may be hepatization. In the policeman, James Hughes, the same dulness on the left side was referred to hepatization on account of the sudden illness, and yet it might be tubercle or something else. In the phthisical cases of Eliza Sleuth, and Ann West, a similar dulness on the left side was attributed to tubercle; but the fact was, that the old tubercle had softened and disappeared, and the entire organ had become absorbed. In the young woman, H. S., this dulness of the left side was viewed with great uncertainty; but she died almost immediately

after admission, and then a vast amount of pus was found, which had, however, produced no bulging of the intercostal spaces during life, nor any disposition to lie on the affected side, (though these symptoms are by some considered essential;) she generally, indeed, lay either on her back or on the opposite side. The almost universal dulness and non-expansion of the right side of the patient William Prentice, who was admitted after a previous attack of pleurisy was likewise viewed with doubt. In order to test whether it were fluid or solid, my surgical colleague, Mr. Langstone Parker, was requested to introduce a small trocar, but nothing appeared from that puncture, and, from all that can be learned of the past history of the man, it may either arise from carnification, or tubercle, or effusion in the pleura, or obliteration of the lung. I still include pleuritic effusion of a more or less solid character in the list of possibilities; because, although the discovery of liquids by the trocar be a positive proof of their presence, the non-discovery of them is no proof of their absence. At the very points where the thrusts are made, there may be solid adhesions, while in other parts, where the pleural surfaces are free, the effusions may be in great abundance. This fact is again and again witnessed by those who are engaged in *post-mortem* inspections. You must avoid drawing positive conclusions from any merely negative facts elicited by the trocar. As little can you puncture again and again in such a situation with the view of obtaining more positive evidence, and, as to being guided by the bulging of the intercostal spaces, such a sign can only occur in the most extreme cases of liquid effusion. The use of the exploring needle has been suggested by some persons as a very facile mode of diagnosing all such diseases; but I have seen such unpleasant results from it in certain cases, that until a vast amount of encouraging evidence is laid before me, I cannot recommend its indiscriminate employment to my pupils. In short, except in safe situations, I view with little favour, this proposal of thrusting a hollow dagger through the human body, as you would thrust a taster through a cheese; because I feel that on many occasions, a dormant, scirrhus, or other less complex tumour might by such means be excited into an active cancer, not to mention other contingencies. You will therefore see the importance of endeavouring to establish, in any given case, what are the recent and what are the old symptoms. From the number of old and advanced cases, brought to public institutions, in which the recent symptoms, and the old pathological changes induced by former disease, are confusedly mixed up, the hospital physician frequently finds himself at a great disadvantage; because, on the one hand, he cannot rely upon the patient's own history of his case, and on the other, if he applies for its previous history to the former attendants, his objects for doing so are liable to misconstruction unless he be personally acquainted with them.

PNEUMONIA, as already observed, is a much more formidable form of disease than the one just treated of. Its causes are of same as those of bronchitis, but, generally speaking, they are more severe in degree, and

produce serious consequences in proportion to the plethoric condition of the patient. No class of men, perhaps, are more frequently victims to this disease, in an intense degree, than those brawny labourers exposed to work in damp excavations. The attack is ushered in by shiverings, thirst, and other febrile symptoms; these are followed by difficulty of breathing, dry cough, heat, and, it may be, pain in the affected part; afterwards the face will assume a dark flush, while the lips may be blue, and the expectoration that accompanies this state of things will sooner or later be tinged of a rusty red. The pathological changes indicated by such symptoms are,—firstly, by the shivering, &c.—depression of the heart's action, and an accumulation of the mass of blood in the internal parts; by the febrile symptoms, reaction; by the difficulty of breathing, dry cough, and heat, are indicated an acute engorgement of the lungs, causing irritation, but as yet no effusion; the dark flush shows imperfect oxygenation; and the rusty coloured sputum, an escape of the red blood from the engorged and dilated capillary vessels. As to percussion, it will yield a dull resonance over the affected part, and the stethoscope will furnish the following concomitant evidences,—viz., in the first stage of simple engorgement, without effusion, scarcely any respiratory murmur at all; in the second stage of effusion a small crackling noise, as of minute bubbles bursting in a tenacious fluid; in the third stage of complete consolidation, no respiratory murmur, or any other sound whatever; and in the fourth, or curative stage of absorption, a return of the crepitating sound, followed by the natural murmur. The combination of these methods of inquiry can leave little doubt in any case of pneumonia, unless there have been previous consolidation, &c., in which event we have to encounter all the difficulties already alluded to. Each symptom will, of course, be of greater or lesser severity, according to the degree and extent of the inflammatory action, which sometimes may be so mild as only to involve a very limited portion of the lung, while at others almost the whole tissue may be subjected to the morbid action. I have sought to picture it in a severe type, in order to give you a marked impression on the subject; at the same time you will please to recollect, that limited attacks may frequently occur in the course of other diseases, such as fever, but especially during phthisis, that may be scarcely at all recognized, though it is of the very greatest importance that they should be detected, and subdued. The secondary consequences upon other organs arise, as you may anticipate, from obstruction of the circulation. The heart first becomes oppressed, makes violent efforts to overcome the obstacle, and, by its ineffectual efforts, increases the local inflammation. Meanwhile, from the stagnation of blood in the general system, and from the vitiated constitution of that blood preventing the ordinary secretions from being carried on, serum may become effused throughout the cellular tissue, and on the serous surfaces, while urea and acrid bile remain in the system to react again on the already poisoned blood, and to induce fresh complications. Such a case, having already run on

through most of these stages before admission, was presented to us in the little girl Catherine Bates, aged 12. In her we had universal dulness; faint and rapid action of the heart; a pulse of 120; anasarca, both of the legs and face; and respirations to the number of not less than 58 in the minute, yet all these were happily subdued by the antimonial treatment, as beautifully indicated in the descent of the respirations from day to day, first to 50, then to 40, and to 20, 18, and 16 successively. In the case of Eliza Sleuth we witnessed the total disappearance of the left lung under phthisis, the greater part of the right involved in it, and the remaining portion rendered useless by a concluding attack of inflammation. Also, in the instance of Ann West, whose left lung was likewise reduced, by tubercle, to a mere pouch at the top, the same as Sleuth's, we found the right one intensely inflamed, even after the patient seemed to have improved a good deal under the cod-liver oil. The latter onset was very sudden; she had little stamina to bear much active treatment, and would have sunk very soon under depressants. The chief features here, during the termination of life were,—blueness of the countenance, anasarca, small pulse, cold feet, and large universal mucous rattles. Most of the phthisical cases that terminate abruptly, prove fatal from the supervention of pneumonia in the remaining sound portions of lung, and therefore it becomes of great consequence to watch for its approaches throughout the whole treatment. In the remarkably favourable case of Hannah Lewis, decided measures were resorted to, even under all the weakness of phthisis, and the successful termination of that case must strengthen this view of the subject. In the first stage of engorgement, although the lung is found of a brilliant scarlet colour, and exuding blood at every cut of the knife, yet it is not altogether deprived of air, for, upon being squeezed, numerous bubbles make their appearance, along with the blood; but in the latter stage of consolidation there is a complete closure of the proper spongy structure of the organ, at first from excess of blood, compared to the structure of liver, and so named the red hepatization, afterwards, from a disappearance of the red particles, becoming grey, and, lastly, quite a pale pink, like the simple fibrinous organization. If such exudations be rapidly enough broken down, and absorbed, before the proper texture be obliterated, then the lung may be restored almost to its pristine condition; but, if permitted to press on the delicate walls so long as to have caused *them*, on the contrary, to be absorbed or atrophied, the adventitious tissue will remain as a fixture through life, and deprive the individual of a certain proportion of air at each inspiration. The respirations will, therefore, become habitually increased in number, while local dulness will be apparent. As already remarked, this dulness will sometimes lead, under other acute attacks, to sundry mistakes as to the presence of tubercle or actually existing inflammation. Such mistakes are chiefly to be avoided by a consideration of the general history and constitution of the patient; yet the certain fact can never be demonstrated until death

reveals the existence of some ancient solidification of the above kind. Thus, in the case of John Schofield, who was admitted with flushed and puffy countenance; much heat of skin, especially on the chest; great dyspnoea, so as to require propping up in bed, with pain on inspiration; anasarca, rusty sputum, and a pulse of 120; we had dulness, much more extensive than seemed consistent with the recency of the attack. Pleuro-pneumonia was at once diagnosticated, and for that he was treated with blisters and antimony, but, though the more positive symptoms of acute inflammation were soon thereby subdued, the same dulness remained. It was now a question whether this dulness arose from a deposit of tubercle or plastic lymph. The general feebleness and flabbiness of the body seemed to plead, in some degree, for the first, but at the same time the absence of emaciation rather pointed to the second. After having rallied from the pleuro-pneumonia, however, he imprudently exposed himself, half naked, to the cold air; this induced a return of the malady, under which he very rapidly sank, and, on examining the lungs, a most beautiful and interesting spectacle was displayed of pneumonia in all its stages, from the brilliant scarlet of the recent attack, to the red, the grey, and the tawny hepatization of former ones. It was obvious that he had had the disease in past times, again and again, and that, being not arrested, it had run on to its natural result of consolidation. As, however, he could give no definite history of his former ailments, a doubt necessarily existed as to the precise nature of the solid matter; fortunately this doubt was not of a nature to interfere with the course of treatment.

The management of these disorders will be the subject of another lecture.

ON EPILEPSY.

A PAPER READ BEFORE THE MIDLAND BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION, AT DERBY, DECEMBER 4TH, 1851.

By JOHN HITCHMAN, M.D.,

Member of the College of Physicians, London, Superintendent Physician of the Derby County Asylum.

GENTLEMEN,—It would ill become me to encroach upon your valuable time by a dissertation on the history and literature of epilepsy, or with a description, however graphic, of the symptoms of the malady, since with these every gentleman in the room is as familiar as myself. However tempting the theme may be once again to revert to those studies which delighted us in youth, and which have been the solace of some leisure hours in manhood, respect for your superior attainments forbids its indulgence. You cannot now afford the time to admire the elegance and truth with which Aretæus sketched this disease, or to pause over the singular skill of Læcretius, who, in depicting the malady, blended the beauties of poesy with the rigid requirements of scientific narrative; or even to discuss the

exact meaning of those phrases in the divine record which seem to give a spiritual significance to this corporeal ailment, but which, traced to their roots, in strict comparison with the existing opinions of the then age, might admit of an interpretation consistent alike with the facts of modern science, and with that beneficence and "good will to man" which the inspired word so abundantly reveals. Nor dare we now glance at a history which comes down to us through so many ages, or revert to the opinions of writers whose essays are numbered by hundreds. If there be any book-loving archæologist present who may desire a statement of such opinions, I would respectfully refer him to the erudite article "On Epilepsy," in Dr. Copland's Dictionary, simply stating that he may there find reference to more than two hundred writers, and yet after reading all their works, he may feel that the disease stands before us now as inscrutable, and as incurable as ever.

My object in reading this brief paper is the humble one of placing before you the particulars of three epileptic cases which have fallen under my notice, and of soliciting your valuable opinions upon the facts they contain. I wish also to contrast their pathological appearances with some other cases of extensive cerebral lesion in which no epilepsy was present, for I think it is by such comparisons alone that we can arrive at safe inductions. In the onset, however, I wish also to add, that pathological changes must be considered with great caution, and in an analytical spirit, or assuredly we shall be led into many, and grave errors. To elicit your inferences upon facts which have fallen under my own notice, and thus to be benefitted by your experience and more matured judgment, is the reward to which I aspire for occupying this prominent position before so distinguished an association.

Of three cases, then, one was found dead; one died in an epileptic paroxysm, or rather from the coma, and exhaustion which followed; and the third from pulmonary consumption.

The first, H. D., was found dead in bed. She had retired to rest in her usual health. She was 50 years of age, and had been the subject of epilepsy for twenty years. Her intellect had become greatly weakened from this cause, and she was partially paralyzed in the left leg. The autopsy revealed the following appearances:—The body was well nourished; the lips were livid, and the neck, especially at its posterior, and dependent positions was of a blueish hue, not from bruises but from venous gravitation, and ordinary *post-mortem* change. She was examined at two o'clock P.M., eight hours after being seen in the morning. The same marks which characterised the neck were also present down the back and other parts. The calvarium was normal in shape, and of average thickness. The dura mater was healthy. The arachnoid membrane was not thickened or otherwise diseased. The pia mater was congested with blood, and the brain generally shared in this condition, in all probability induced by the mode of death. The upper surface of the convolutions of the cerebral hemispheres presented here and there hard knotty indurations, which varied in size from that of a

pea to a large bean, but of a corrugated and rounded figure, while others were more elastic and smooth. These indurations proved to be small cysts, and the difference in their characters of hardness and form was found to arise from the circumstance, that the harder and corrugated ones had lost their fluid, and now contained a white grumous material, resembling an impalpably fine mortar, and in which, by the aid of the microscope, could be seen a large number of very minute crystals, having a rhombic figure. Those possessing fluid contained within this a few clear spherules, of varying microscopic size, adhering to their inner surface, but none on their exterior; each cyst was distinct in itself, forming in this respect a great contrast to the acephalocysts occasionally found in the uterus and other organs, indeed their solitary character induced my friend, Dr. Hodgkin, and myself, to look most carefully for that curious entozoon, the *cysticercus cellulosus*, which has been occasionally found in solitary cysts occupying the brain and the eye of the human subject, but without success. A small solitary cyst, less than a pea, was found on the upper surface of the left lobe of the cerebellum. The vesicular neurine of the convolutions exhibited no disease beyond the immediate contiguity of these little bodies, and even at that spot nothing further than a depression, caused by their presence, could be detected. Whether this depression was induced by simple pressure, without any loss of nervous substance, or whether it had given rise to atrophy, could not be well determined upon. I am inclined to think the latter. The vesicular and fibrous portions of the brain were each much congested with blood, which we regarded rather as a moribund effect than anything else, (as the patient had died, in all probability, from asphyxia,) and we discovered no other change until we reached the left ventricle, where, resting upon the corpus striatum, was another cyst, of considerable magnitude, as large, indeed, as a pigeon's egg. In this large cyst the walls had a distinctly laminated texture, and small clear globules or spherules were studded over its inner surface, resembling the "hyaline" which has been so fully described as to its properties by Barry and others, and which, in truth, were young cells, slowly forming into other acephalocysts. The corpus striatum around this larger body was softened in its structure, and had undergone some diminution. The brain presented no other disease. The choroid plexuses, in common with the blood-vessels of the brain generally, were in a congested condition. The right lung was gorged with blood, and the patient was considered to have died from "pulmonary apoplexy," in fact that was the verdict returned (from medical testimony) at the Coroner's inquest. No other disease was found in the chest, and the viscera of the abdomen were remarkably healthy.

In contrast with the above case, was one which I saw in 1849, in which there were spiculae of bone protruding from the inner periosteum of the skull (dura mater), and resting upon the brain—i.e., resting upon, although not piercing the pia mater; the cerebral lobes were of unequal size; the superior longitudinal sinus was

literally encased in bone; the choroid plexuses contained small cysts, and the basilar arteries were loaded with atheromatous deposits; and yet this patient had never experienced epilepsy. On the 23rd of January, 1849, I examined an epileptic in whom there was the same singular irregularity in the size and form of the cerebral hemispheres. In this case, the left anterior cerebral lobe was very much larger, and three quarters of an inch longer than that on the right side; the vesicular neurine of both lobes was soft, and varied in hue, from a dark brown to a pale fawn colour; the middle lobe of the cerebellum was much shrunken and atrophied, and had a pale macerated appearance, like to animal structure which had been long immersed in fluid. But in this case, the pituitary gland was extensively disorganised, degenerated in fact, through the greater part of its structure into a gritty, earthy substance; and the clinoid processes of the sphenoid bone were so elongated as to project and to press upon the superjacent parts of the cerebrum. These two latter cases are, I think, highly instructive by contrast, as *proving* that the inequality in the weight, size, and form of the anterior cerebral lobes, belongs rather to the lesions of insanity than to epilepsy. For I ought to have stated at the outset, the important fact, that the patients to whose autopsies I refer, were not only epileptic but insane. It would certainly vitiate all our reasonings if part had been insane and part otherwise; but as all were of unsound mind in an equal degree, as the conditions of each were equal, I do not think this circumstance will much invalidate the usefulness of the facts recorded.

The second case who died from epilepsy, on the 18th of December, 1849, was 56 years of age. She had been insane eleven years, and epileptic forty-eight years, the epilepsy having been produced by a blow. When 8 years of age she was knocked down by an infuriated cow, and her frontal bone fractured by the blow. In the autopsy, the calvarium was found to have a deep indentation of a triangular form in the centre of the frontal bone; this was limited to the first table, as no corresponding mark was visible on the cerebral surface of the bone. The inner table was deeply grooved by the meningeal arteries, and had become so thin as to be diaphanous. The base of the skull was of a contracted form; the ethmoid process, "*crista galli*," was very large and projecting; and the clinoid processes of the sphenoid were curved and irregular; the dura mater was firmly adherent to the skull; the arachnoid was opaque and thickened; the pia mater much congested; the Pacchionian bodies were very large; the pituitary body was atrophied, and in a degenerate condition; the medulla oblongata was much congested with blood, and I should have said, that the lateral ventricles were devoid of fluid. The heart was small and flaccid, and its tricuspid valves were diseased and thickened. The other viscera of the body appeared healthy. I wish to contrast this with another autopsy conducted by me in 1845. E. L. died from a fungoid tumour of the dura mater. She had exhibited great passiveness of character and simple imbecility of mind. She had for more than one year suffered extreme pain on the left

side of the head, along the lower anterior edge of the parietal and across the temporal bone, at which point she had received a severe blow in a quarrel some five years prior to my seeing her. When I first saw her, the left eyelid was paralyzed, and drooped over the eye; the pupil was enormously dilated, and vision was extinct. For a fortnight before she died, she experienced great pain and difficulty in the act of deglutition, and for the three latter days of her existence, was unable to accomplish it. For the same period, the left nostril was insensible to snuff and some other irritants. On examining the skull after death, it was evident that the blow had left a deep scar over the left temporo-frontal region; this appeared to have excited inflammation of the dura mater, and to have given rise to the tumour, which has been already named as the cause of her death; for although it was not immediately opposite the seat of injury, yet the membrane from a point opposite to the external scar, was most intimately adherent to the bone. The tumour, which was placed somewhat obliquely in the base of the skull, pressed on the left optic nerve at a point anterior to the outer edge of the crus cerebri, as it was passing forward to join its fellow nerve. The scirrhus thickening was, however, more conspicuous, harder, and larger, upon, and in front of, the petrous ridge of the temporal bone, embracing within its substance the semilunar ganglion, protruding forwards and inwards, pressing on the outer edge of the cavernous sinus, and completely imbedding, anteriorly, the first, third, and second divisions of the trifacial nerve, as they respectively passed to the cavernous sinus, the foramen ovale, and the foramen rotundum. In consequence of some unavoidable delay, the brain had become too soft for a satisfactory examination. It will strike you, how completely the disease was illustrated by the neuroscopic appearances; in other words, anatomically, by the loss of sight on the same side, as it pressed on the *outer* edge of the optic nerve prior to its conjunction; in the paralysis of the upper eyelid, as it encroached on the motor oculi nerve, on the ophthalmic branch of the fifth, and ultimately interfering with and interrupting mastication and deglutition, by its pressure on the superior and inferior maxillary nerves, and probably, from the same cause, destroying sensation in the lining membrane of the left nostril, as the throat and nose were free from disease.

A blow upon the frontal bone immediately produced in the former case an epileptic paroxysm, which occurred at intervals through forty-eight years, ultimately inducing mental derangement and death. A similar force at the junction of the parietal with the temporal bone did not originate epilepsy, but gave rise to a malignant tumour, which encroached upon and destroyed some of the agencies of vision and muscular action, and, by mechanical contiguity, impaired the intellectual manifestations of the brain, and finally destroyed life. How are we to explain these discrepancies? Are such phenomena limited to diseases of the encephalon, or are they found to exist in the other structures of the body? Can a rational explanation be found in the circumstances attendant upon the injury? or will our

present knowledge of the structure and functions of the varying parts involved in the respective lesions furnish it? In the latter case, anatomy fully explains the entire range of objective phenomena; but how and where are we to seek for an elucidation of the presence of epilepsy in the one case, and of a fungoid tumour alone in the other? I trust these questions are worthy the attention and the thought of intelligent medical men;—that you will not deem me frivolous in bringing them before your notice; but that you will kindly extend to me your indulgence whilst I proceed to the narration of the third autopsy, and to the detail of some facts connected with the previous history of the case.

M. A., who died from pulmonary consumption, in 1850, had been epileptic to an extraordinary extent for many years, especially during the six months prior to the manifestation of the thoracic disease; in the month of January preceding her decease she had as many as one hundred and sixteen paroxysms of epilepsy, reckoning that as a distinct fit which was followed by consciousness, for however brief a period the consciousness might have lasted. In this case, the severest I ever witnessed, there was no cerebral lesion, beyond opacity and thickness of the membranes of the brain, effusion of serum between the convolutions and into the lateral ventricles, and a very hypertrophied condition of the pituitary body. This organ was, however, most extensively diseased, and is a structure of far greater importance than its situation or its size might, *a priori*, intimate. This patient formed one of nine that I selected for especial observation, with a view to determine if any, and what amount of influence, the moon might exert in the production of the epileptic paroxysms. I have great faith in popular notions; that is, I believe they frequently contain a nucleus of truth, however much such nucleus may be covered with incrustations of error and folly; and, at all events, the supposition that such influence was exerted could only be disproved by carefully observed facts. Accordingly, nine epileptics were watched most assiduously for two months, and the facts duly registered. I shall weary you only with the particulars of one month. In no one day, nor within any one week, did *all* the nine cases experience an epileptic seizure; but eight out of the nine became epileptic during the first fourteen days of observation. M. A. had fits every day through the entire month; on some of these days she was scarcely exempt from its influence during any part of them. On the day of the new moon she had two paroxysms; on the seventh day of the moon's age she had five paroxysms; on the day of the full moon she had three fits, and on its entering its last quarter two paroxysms; on the recurrence of a new moon, two fits; on the twelfth day of the moon's age she had six paroxysms, and on the twenty-seventh day six fits. On the day of the full moon only two patients out of the nine had seizures, while on the seventeenth day, on the twenty-third and twenty-ninth days of the moon's age, four of the nine were beset with the malady. On no one day were more than four afflicted; and the largest number of paroxysms experienced in

twenty-four hours by one epileptic was six. We therefore infer that although epilepsy is paroxysmal in character, it has no direct relationship to the condition of the moon, except, perhaps, in some rare, exceptional, and highly sensitive cases. It is, however, a remarkable fact that this patient, M. A., who had been epileptic for many years, who, through the entire period above referred to never passed a day without a fit, and who in one calendar month experienced above a hundred paroxysms, never was epileptic during the last six months of her existence. From the day that inflammation of the lungs set in until the day of her death from tubercular disease, she was free from the former malady. She was watched night and day by trustworthy nurses, under my own immediate supervision, and, therefore, upon this statement you may fully and implicitly rely. Here again, as it appears to me, an interesting question springs up,—What condition excitant of epilepsy was removed by the deposition of tubercle on the lung?

Is it a law that no two diseases can exist in the system at the same time?

I have purposely avoided, on the present occasion, all allusion to treatment in the above cases, as it would have lengthened my paper, and unduly prolonged the discussion of the subject. Perhaps I may be allowed to state, that in many diseases, some of our most successful remedies are those of whose especial action we are ignorant; quinine in ague, for instance, and colchicum in rheumatism; but it would be both unwise and unsafe to employ these or any other remedies in an empirical manner, for the experience of most men will point out cases in which either of the above remedies would be useless or injurious if so employed. I have known ague resist the influence of quinine for many months, owing to two omissions on the part of the practitioner. First, neglect of the digestive organs; and, secondly, the employment of the medicinal agent in the form of a hard pill, instead of in some fluid, slightly acidulated with sulphuric acid. Empirical routine, at all times dangerous, would be especially so in such a grave malady as epilepsy. Its frequent incurability has sometimes prompted practitioners to adopt rash measures in its treatment. There is scarcely a drug in the whole range of the *Materia Medica*, or elsewhere, that has not been used in epilepsy; from the skin-dyeing nitrate of silver, and the heart-subduing digitalis, down to the more dangerous vagaries of the homœopathic treatment, and its no less formidable sister, “the water cure.” *Hydro-pathic* treatment—(ὕδρ παθος)—“water disease” treatment! How expressive! Alas! how true! Such rashness should not be. Sudden deaths are largely on the increase in this country; and I think, with Dr. Granville, they are mainly due to the dangerous popular delusions of homœopathy and hydro-pathy, on the one hand, and, I fear I must add, to empirical routine on the other. Each case of epilepsy demands its own especial treatment; and if to every case we administer the same drug, whether it be indigo, valerianate of zinc, digitalis, turpentine, cotyledon umbilicus, or the sumbul; or if in each case we tie the carotid arteries, open the trachea, or bleed heroic-

ally from the temples, we shall most assuredly do more harm than good. Whichever of these remedies may be adopted as our agent, it will prove mischievous, if we rely solely upon it in the treatment of every epileptic who may come before us. Yet either of these remedies may prove successful in some one especial instance. Turpentine has been of great service; the cotyledon umbilicus, introduced to the profession in such a judicious manner by Mr. Salter, of Poole, is a valuable drug; and the "sumbul" of Dr. Granville will, I think, prove advantageous to those deplorable cases of paralysis and epilepsy which seem to arise from excessive sensual indulgence. It is the high mission of rational medicine—indeed it is its distinguishing characteristic—to treat each case according to its respective peculiarity, uninfluenced by any passing fashion, whatever that fashion may be, whether it find its exponent in a globe of dust, or in the gaudy saloons and cold fountains of a Hydropathic Symposium.

My task is now done. I am deeply sensible of its many imperfections, but its highest aim has been to elicit information, and to show by a feeble example, how readily a small part of each individual's experience may be made conducive to the general good. Perhaps I may be permitted to add, that the last case related, suggests to us the propriety of extreme caution in drawing inferences from isolated cases, especially as regards therapeutics. Had my poor patient been mesmerised on the day preceding the inflammatory attack, or had she swallowed some homœopathic globules of *cenanthe crocata*, stramonium, hydrocyanic acid, or any other drug said to *excite* convulsive disease, (*similia similibus curantur*,) would not the disciples of Mesmer, or Hahnemann, at once have inferred, and proclaimed—yes, proclaimed! through all the saloons of fashionable gossip, that their "passes," or their "globules," had *cured* the epilepsy, and that the pulmonary disease was an accidental sequence, having no influence whatever upon the former malady? Let us avoid this vice of empiricism: and, being regardless alike of the shining allurements of dishonest gain, or the false glare of a fickle popularity, let us walk together with brotherly love in that narrow but bright path of philosophic induction, which Harvey, and Hunter, and Jenner have trodden before us, and there will remain for us the happy consciousness of duties faithfully performed, and the well-founded conviction, that the talents respectively committed to us have been employed, and employed only, in those high purposes for which they were originally bestowed.

A CASE OF

POISONING WITH ARSENIC ACID.

By J. SKEVINGTON, Esq., ASHBOURN.

I was sent for about nine o'clock, A.M., on the 14th of November, to attend Mrs. B., aged 53 years. On my arrival I found her vomiting violently; she com-

plained of great heat and pain from the mouth to the stomach; was very faint, and had cold perspirations. I asked her what she had taken; she replied, nothing but a cup and a half of tea, containing a little carbonate of soda, and buttered toast. She complained to the servant that it tasted very peppery; and in about three minutes after drinking the tea she began to vomit. The pulse was about 120 beats in a minute, small and irregular. The skin was cold and clammy. Purging came on in about a quarter of an hour, with intense pain in the abdomen, more particularly on the left side. I ordered her into bed, and applied bottles of hot water; she soon became warm, and afterwards experienced a burning heat of the skin; the respiration was performed with difficulty; the eyes were injected with blood, and appeared as if they were leaving the sockets with intolerance of light; there was not any paralysis or exanthemata; the tongue and fauces in many places had the appearance of being recently touched with lunar caustic; there was great difficulty of swallowing, with violent pain in the head, and cramps of the extremities; the vomit was of a bilious character; the anus was excoriated; the urine was scanty and scalding, scarcely making any for two days; the voice was altered, and hoarseness continued for a fortnight.

The servant, a woman about 35 years of age, had taken some of the same tea, and was attacked with similar symptoms, though not quite so severe. On the third day she was taken with violent pain and swelling of the tongue, lips, and face, which continued for several days.

I gave both patients an emetic of ipecacuanha (gr. xxv), and in half an hour I began with half-ounce doses of the hydrated peroxide of iron, taken every half hour. Mrs. B. took five doses, and the servant took three. The urgent symptoms of poison having subsided, they were both very ill of inflammatory fever, which, I am happy to say, gave way to the antiphlogistic treatment, and they were convalescent in a fortnight.

The analysis of the tea which remained was carefully performed by Mr. THOMAS COCKER, chemist, which proves the quantity taken.

A Case of Poisoning with Arsenic Acid or Arseniate of Soda.

At the request of Mr. Skevington, I took charge of the remainder of the tea which had been drank by Mrs. ——— and her servant. There were about six ounces of it, and I tested it for arsenic.

1.—Tested the tea with blue and red litmus papers, and found it slightly acid.

2.—Prepared the fluid by adding acetic acid to coagulate the milk, &c., boiled and filtered through paper in the usual way. When quite clear, and as free from organic and foreign matter as I could obtain it, I added the hydrosulphuret of ammonia, which produced a rich bright yellow, the sesquisulphuret of arsenic, which was soluble in ammonia, forming a nearly colourless solution.

3.—Added the ammonio-sulphuret of copper, which produced a greenish blue precipitate; not the usual pale green—Scheele's.

4.—Added the ammonio-nitrate of silver, which produced a reddish brown, or chocolate; not the usual colour—canary yellow, which appears with arsenious acid. The result surprised me, because it proved the presence of arsenic acid, not arsenious or common white arsenic of the shops; repeated the experiments several times, but always with the same results.

5.—I then poured some of the tea which had been previously prepared, into a porcelain dish, added a proper quantity of hydrochloric acid, brought it to near the boiling point, put in some thin bright copper, which immediately caused a deposit of arsenic upon it.

6.—I then introduced the sulphuret of arsenic into a glass tube, with black flux, decomposed and sublimed it, which proved to a demonstration the presence of arsenic.

But the question for my consideration was,—How could arsenic acid, an article never kept in retail shops, and confined exclusively to the chemist's laboratory, have got into the tea pot? This I was surprised at, and for some time puzzled with, until I began to reflect that carbonate of soda had been put into the teapot along with the tea, and that arsenious acid was capable of uniting with it, and forming a neutral salt, the arseniate of soda, which is easily soluble in water, and this would account for its slight action on litmus paper. The brown precipitate of arseniate of silver by ammonio-nitrate of silver, and the greenish blue precipitate of arseniate of copper, in neutral solutions of arseniates, are both very characteristic tests.

Lastly.—Measured two ounces of the prepared tea, added sulphuretted hydrogen, filtered, dried, and weighed the precipitate; weighed eight grains, or about equal to six grains of white arsenic of the shops. The patient, therefore, must have taken in the eight or ten ounces of tea, about half a dram of arsenic.

THOMAS COCKER.

Ashborne.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CASES ADMITTED UNDER DR. DAVID NELSON

Reported under the terms proposed by the Association.

By OBSERVATOR.

Case of Hemiplegia.

FROM the frequent occurrence of paralytic cases, and the very frequent incurability of such cases, it is probable that by some persons (particularly those who have witnessed many really or assuredly incurable cases) a too general opinion has been formed, namely, that nearly all are hopeless, or, at best, only admit of slight palliation. Instances of recovery are sometimes re-

corded, and to add one, of at least comparative recovery to that number, in the hope that it may contribute some degree of encouragement to treat patiently and perseveringly this truly pitiable class of suffering fellow-mortals, affords me much pleasure in reporting the following case:—

John Barrett, aged 35, of phlegmatic temperament, was admitted an in-patient of the Queen's Hospital, under Dr. Nelson, on the 20th of December, 1850. He was completely insensible when admitted, but, according to the statement of his friends, after taking supper on the 17th, he went to bed in seemingly good health, not making any complaint; on the following morning he was called, and made a correct reply, but on getting up he fell down, and became insensible, remaining so until about the 21st.

Symptoms.—Loss of sensibility and motion; paleness of countenance; pupils contracted and sluggish; slightly increased heat of the head; the mouth was drawn to the left side, and the muscles of the right side unnaturally soft; the right arm and leg were more especially incapable of any movement, but a slight degree of sensation existed, as a slight expression of countenance indicated when he was pinched; the bowels were constipated, but the urine passed involuntarily; pulse slow and full, 65 to 70.

Diagnosis.—Apoplexy, with hemiplegia.

Indications.—To prevent effusion and inflammation, and to promote absorption.

Treatment.—The head was shaved, and cold applied constantly; six leeches were applied behind the ears, followed by blisters; a pill of calomel and croton oil, followed by a draught of sulphate of magnesia, jalap, and senna, was administered every second hour.

21st.—He seemed somewhat better. He took two grains of calomel every second hour, and continued the draughts. Also a seton was inserted.

22nd.—Improving a little, now having intelligence enough to open his mouth, but could not protrude his tongue, which, with his teeth, was coated with a black fur. The right arm and leg were utterly powerless. Continued the medicines, with a draught of ammonia occasionally.

23rd.—He still gradually improved, and had taken food several times. The skin was a little more sensible. Continued the medicines.

24th.—The bowels had been freely opened, but no mercurial effects had been produced. The pupils were natural. The tongue, which he drew out with his left hand, when asked to show it, was brown and dry. The hemiplegia continued, and he answered "yes" to every question. Pulse 80, softer. Continued the medicines.

27th.—The tongue was clean, but the other symptoms remained the same. Continued the medicines.

31st.—Seemed about the same. He continued the mercury, with an aperient draught occasionally.

January 3, 1851.—The head was cool, and the tongue clean. He had gone twice to the water-closet, with assistance; and had pronounced his own name. Pulse 88, full, and firm. Continued the medicines and rest.

10th.—He had much improved, and could occa-

sionally answer questions correctly. Also he had in a slight degree recovered the power of the right arm and leg. Continued the medicines.

14th.—He was sitting up, and could move both arm and leg a little, but had a stupid and idiotic appearance. Continued the medicines.

17th.—Still improving, could answer simple questions, and could walk with assistance, dragging his right leg. Continued the medicines.

24th.—The calomel and aperient were omitted, and he took sulphate of zinc three times a day, and blue pill and colocynth every night, while he rubbed in a stimulating liniment. At this state he walked out in the grounds with a stick, hanging his right arm, and dragging his right leg.

28th.—Still improving, but some dragging of the right extremities continued, with dullness of intellect and imperfection of speech. Appetite very keen. He now began to take phosphate of iron, instead of sulphate of zinc.

Up to the 4th of March little change occurred. He then left the hospital in a fat and hearty condition. His speech was still thick, his tongue was protruded towards the left side, and all the powers of the other side remained impaired, yet he could raise his right arm to his head, walk quickly with a stick, and could make himself generally useful, although he had lost much of his natural vivacity.

Such cases are always doubtful in their results, but the remedial measures were in this case so far successful, consisting chiefly in the use of derivants, and such agents as abate inflammation, and promote absorption; and what appears to be of great importance, the enforcement of perfect quietude, not admitting even of any unnecessary interrogation, which instead of improving the patient by rousing him, only injure and disturb him by the cerebral exertion called forth.

In this case was the remarkable, but hitherto unaccounted-for symptom of answering "yes" to every question.

Case of Carcinoma of the Pylorus.

DREADFUL as is this malady, when seated externally and where it is frequently amenable to surgery as a palliative or curative means, still more fearful is it, when an internal organ is the seat of attack, particularly when the tumour is so situated as not to produce symptoms clearly indicative of its presence, thereby concealing its nature until remedies are of no avail. In this case the tumour occupied the pylorus, but could be felt only sometimes, and some examiners who did not feel it denied its existence; hence the importance of a close examination, especially by palpation as a confirmation of the diagnosis founded on other symptoms, as is illustrated in the following case:—

Joseph Shay, aged 48 years, of bilio-nervous temperament, a hawker, became an in-patient of the Queen's Hospital, Birmingham, under the care of Dr. David Nelson, on the 25th of October, 1850.

He stated that his illness was of four months' duration, and complained chiefly of constipation and persistent vomiting after taking food.

He declared that he had been a regular liver, and had travelled much in the open air in his vocation; but a gentleman was present in the ward who recognised him, and affirmed that he had been an inveterate dram drinker; this was confirmed by his relatives, who reported him to have led a very abandoned life, being frequently drunk upon rum for several successive days, without tasting any kind of food. He was very thin; countenance of a straw-coloured sallowness, which, with the wrinkles of his forehead, made him appear older than he was. He had a dry cough; but the pectoral percussion was good and the heart's sounds natural. The tongue was pink and furrowed; the vomiting continued as previously, and the constipation yielded only to aperients. There was tenderness of the epigastrium, and something hard could be *sometimes* felt in the region of the pylorus. The skin possessed a natural degree of heat; pulse 100, small and weak.

Diagnosis.—Scirrhus or cancer of the pylorus.

Indications.—To relieve local congestion and allay irritability.

Treatment.—Application of leeches over the epigastrium and the administration of an aperient pill every night, with a draught of calumba, bismuth, conium, and opium, thrice a day. Ordered mild food in very small quantities.

28th.—The vomiting was only slightly relieved; cough continues; pulse 78; continue the medicines.

November 1st.—He became worse, all food and medicine being rejected as soon as taken, the bowels were moved almost hourly, and the fæces were dark; tongue remains furrowed; pulse 100. Four more leeches were applied, and nothing but hydrocyanic acid administered.

5th.—It was reported that the stomach rejected everything. He had also shooting pains; and on this day Dr. Nelson, with the resident officers, distinctly felt a hard tumour in the pylorus. It was not so easily distinguished at other times. He was ordered a draught of hydrocyanic acid immediately, and an injection of tincture of opium, also brandy in small doses.

8th.—He vomited once and twice the day before; but had severe purging. He took acetate of lead with opium, and his diet was to consist of mutton broth, thickened with rice.

9th.—He continued much the same as to sickness and purging. Medicine continued.

10th.—He was manifestly weaker; and on the 11th was extremely low, scarcely took anything, very indifferent to conversation, and was evidently sinking rapidly. He died on the same day, at six p.m.

Autopsy.—The body was emaciated and straw-coloured; the texture of the heart looser than natural; but the lungs and pleura were perfectly healthy. The pyloric end of the stomach was found to be a large thickened mass, corrugated and lobulated externally, and formed of a carcinomatous deposit, ulcerated at the inner mucous surface, with here and there patches of

inflammation. The disease extended two inches up into the cavity of the stomach, and about the same length down the duodenum. There was a regularly defined margin round the whole circumference of this mass on the mucous surface; and the rest of the stomach and duodenum beyond this margin looked healthy. The liver was pale and fatty, but not enlarged. The bowels and kidneys appeared natural, and the spleen was only a little turgid.

This seems to be one of those cases in which cancer is fairly attributable to frequent large potations of raw spirits upon an empty stomach; whatever else the deposit of cancerous matter may be dependent on, it seems clear that it is generally developed in parts which are the seat of chronic irritation, in conjunction with pressure or constriction. Hence, apparently, its frequency in the neighbourhood of the pylorus.

The emaciation, the straw complexion, and the vomiting, were the chief subjective symptoms that led to the diagnosis, and the discovery of the tumour removed all doubt. Yet, so very obscure was this physical sign, that it was frequently not felt, and seemed to have escaped the notice of those who had previously treated him. It was deep seated, and felt like a floating ball within a bladder full of fluid, against which the finger could only impinge, and then it was lost. The best way of detecting its presence, was to place the fingers on the skin, and by a sudden descent they were felt to come in contact with a body resembling a segment of a hard ball, which so yielded that it could not be pressed. No treatment, of course, could have been of any avail at such a stage of the disease. To allay irritation was all that could be done.

Provincial Medical & Surgical Journal.

WEDNESDAY, JANUARY, 7, 1852.

In the preceding numbers of this *Journal* will be found two letters on the subject of the inspection at present exercised in regard to private lunatic asylums, one by Mr. PERCEVAL, the Secretary of the Lunatic's Friend Society, containing some sweeping charges against all proprietors of these Institutions, the other a courteous and well-timed reply by a Member of the Council of the Provincial Medical and Surgical Association.

The subject is undoubtedly one of great importance. In our private asylums are confined the relations and friends of many families of distinction in the country; indeed, of scarcely any circle can it be said, that no one member is thus afflicted, or likely to be so visited amid the many changes which sadden life's varying

scene. And the inmates of these institutions, too, are people touchingly dependent upon us all for support and protection. They are, to use the words of a recent writer, "abiding in a region where but few rays of hope enter, and are borne along in a course which has no bright horizon such as generally dawns on the elastic minds of the sane, amid the greatest troubles. And yet they are brethren: carried onwards with us by the same river ever flowing towards the ocean of eternity; their bitter cries rise up on high mingled with our careless voices, and both the plaints of the one and the insensibility of the other, are registered there."

The private asylums so indiscriminately abused by the self-styled lunatics' friend party, are divided into two distinct classes, the one owned by medical men—many of them of high character both professional and general,—the other class by lay proprietors, who treat their poor patients, much as the lay impropiators treat the immortal souls in their parishes,—as mere objects of traffic and gain. For these latter and the entire system connected with them we have no word of defence. Indeed, thanks to the able efforts of Her Majesty's Commissioners in Lunacy, the system of lay licences for the purpose of farming out from unions and needy or, it may be, greedy relatives, the insane to board and clothe, is becoming one of the things of days gone by. Till the system be entirely abolished, Mr. PERCEVAL may write without let or hinderance from us.

Of the first class, on the other hand, the houses kept by professional men of experience in this department of medicine, we can, from extensive personal observation, speak in the highest terms of approbation. In any suggestions, therefore, for their better regulation which we may now offer, the friendliness of our motives cannot be misunderstood.

Such institutions are at present visited half-yearly by the Commissioners of Lunacy, and quarterly by the Visiting Justices of their respective counties. At these visitations, the patients are each individually seen, all certificates are examined, and the various domestic arrangements of the house inspected. Visits, however, at such long intervals and with so little acquaintance with the minute economy of the establishment, cannot be productive of that active superintendence which can alone ensure perfect observance of the recommendations which the Commissioners may find it necessary to make. In

illustration of this remark we may observe that an instance came under our own notice, in which the practice of making two male patients occupy the same bed, had been persisted in for years, and not suspected either by the Commissioners or Visiting Justices.

This subject has been recently canvassed by a cotemporary writer,* who fully enters into the various deficiencies in the present system of visitation of private lunatic asylums at which we have thus glanced, and the grounds for an increased inspection of such houses are thus briefly stated.

1. *Frequent visits are necessary to free the minds of the patients of injurious anxiety.*

2. *Frequent visits are necessary to free the minds of the proprietors in doubtful matters of discharge.*

3. *Frequent visits are wanted to settle matters of unavoidable disagreement between patients and their ordinary superintendents and advisers.*

4. *Frequent visitation is necessary to free the mind of the Commissioner of those inaccuracies of judgment which rare visitation engenders.*

On these and similar grounds, which even a cursory acquaintance with the internal arrangements of a lunatic asylum would readily suggest themselves, the question of the expediency of such a fuller inspection of private lunatic asylums as we are now advocating, will we trust, appear to our readers to be fully established.† Still the question how this inspection is to be effected remains to be answered.

On all sides it is admitted that the present working staff of the Lunacy Commission (three barristers and three physicians) are unequal to any additional work. The amount of yearly journeys and other works performed by these gentlemen is, we have reason to know, constant full occupation. And yet it is manifest, that if this increased inspection we are advocating is to be fitly performed, no additional visits of justices or other good natured and unpaid gentlemen will suffice. The work, if done at all, must be done efficiently, be performed by paid officers, servants of a central authority and responsible to such for the regular performance of their duties. The Lunacy Commission naturally suggests itself as the fit board or central authority,—members of the medical profession as the persons

to perform these functions. For however much the varied medico-legal business which now yearly comes before the Commission, makes the present arrangement of a mixed medico-legal board one most desirable, the purely professional nature of the visitations we are advocating renders it apparent beyond a doubt, that physicians of experience in such duties, are the fittest persons to undertake the office.

We believe that all the necessary duties might be fairly performed by four Assistant Medical Commissioners in Lunacy, to whom, say the four military districts of the country, should be assigned, for the diligent inspection of all private lunatic asylums and the examination of matters relating to the welfare of the insane, which might require investigation in the interval of the Commissioner's half-yearly visits.

A similar arrangement is already found to work well in the practice of the Poor-Law Commission, and we cannot think, should the case be duly represented to Her Majesty's Government, that any insurmountable difficulty would be found to arise in its practical application.

WHEN we penned the remarks in our *Journal* of December 10, upon the circumstance of Dr. CALVERT HOLLAND being retained as Consulting Physician to the Sheffield General Infirmary, after having openly espoused the homoeopathic quackery, which we did at the special request of a member of the Association residing in that neighbourhood, we did not for a moment consider that we should be suspected of a wish to "attack" the medical staff of that highly valued Institution. As, however, our comments have been so misunderstood, we take the opportunity of cordially assuring Dr. BRANSON and his colleagues, that nothing was further from our intentions than to impute blame to them in respect of circumstances over which they have no control; and we beg them to accept our assurance of regret that we should have unwittingly caused them any feelings of annoyance.

Reviews.

Memorial of Dr. Mackness. London: Churchill. 1851.

THE volume now before us is one of a class which, in the present day, is becoming far too numerous, though the memorial of the life of

* Dr. H. Monro, *Med. Gazette*, October 31 and December 5.

† Our correspondent E.B. differs in many respects from us; and we trust he will agree to differ in all fairness and courtesy.

such a man as Dr. Mackness, must stand out in bright relief from the host of uninteresting diaries and original letters which are now published, with what intention it is difficult to surmise, as they are neither calculated to immortalize their subject, remunerate their editor, nor benefit their purchasers. It is always pleasant to read the life of a good man, and particularly so when that man has had so many opportunities of improving the spiritual and mental, as well as the bodily condition of his fellow-creatures, as Dr. Mackness seems to have found in his brief career. (He died at the age of 47.)

The medical profession is one which we have always regarded as affording more opportunities than any other calling, for introducing serious thoughts, and assisting the erring penitent or obstinate sinner in his heavenward path; and Dr. Mackness seems to have improved these opportunities to the uttermost. We read of his encouraging the feeble, supporting the wavering, and comforting the broken-hearted, and all in the simple kind way which seemed a second nature with him. His letters to many of the bereaved relatives of his deceased patients are beautifully adapted to raise their thoughts to that world whither their friends are gone before them, and to induce them to rejoice on their account, rather than to mourn on their own.

We hope we have said enough to convince our readers that the "Memorial" is one which they cannot fail to read with interest, and one which we would particularly recommend to young members of our profession, who feel discouraged and disheartened by the obstacles which seem to stand in their upward path; for few men have begun life under more inauspicious circumstances than Dr. Mackness, and few had greater difficulties to contend with; but few—very few, have surmounted them so completely as he did. He was a staunch friend to the Provincial Medical and Surgical Association, and always dwelt on the meetings of that Society which he attended with peculiar pleasure.

In conclusion, we cannot help complimenting Miss Howard on the able way in which she has performed the duty of biographer, and lamenting with her that the medical profession should so early have been deprived of one of its brightest ornaments.

The Nature and Treatment of Softening of the Brain.

By RICHARD ROWLAND, M.D., &c. London: Highley. 1851.

THE diseases of the nervous system have always been approached by practical writers with a well-justified reserve; for where a mystery hangs over the normal actions of an organ, it is not to be expected that the manifestations of its morbid conditions will be appreciated with anything like a satisfactory amount of certainty. For this reason additions to the literature of disease of the brain are few and far between, and when produced are too often found wanting in that precision which is the characteristic of treatises on the diseases of other regions of the body. Softening of the brain is, moreover, a lesion which has been less accurately defined than many other affections of the nervous system, and the term itself has been applied to anatomical changes of quite different pathological significations; the attempt, therefore, by Dr. Rowland, to remodel its history, cannot but be acceptable.

Pathological writers acknowledge several varieties of softening of the cerebral substance, but for all practical purposes it is sufficient to consider, with the author of the present treatise, the two forms of inflammatory and non-inflammatory softening. Of each of these varieties Dr. Rowland describes the distinctive symptoms with great minuteness. One of these symptoms, regarded by him as of great significance, is the reiteration of comatose attacks followed by an almost abrupt return of consciousness; at one hour the patient may be in the deep stupor of apoplexy, in the next, perhaps, he may be conversing freely, and rationally. This rapid alternation of symptoms we have recently witnessed in a marked degree, in a case of inflammatory softening of the brain, the result of excessive and long-sustained intellectual labour. In this instance the coma was profound, even to the extent of producing that peculiar "whiffing" breathing generally considered to be of fatal import.

The lesions of the speech form a remarkable group of symptoms, and present themselves under various peculiarities. Sometimes the speech is entirely abrogated while the patient is rational and conscious of his inability to utter his thoughts. In others there is slow and hesitating articulation, with a greater or less misapplication of words.

Respecting the causes of cerebral softening, Dr. Rowland appears to be in some doubt. Hereditary influence has not appeared to him to be traceable, and temperament has seemed to be inoperative. In reference to sex Dr. Rowland's inquiries elicit the fact, that the female is more liable to it than the male; this is entirely opposed to general opinion. It has erroneously been thought that great mental exertion, and long-continued anxiety of mind, is a fertile source of the disease; but here, again, figures do not sustain the general impression. Dr. Rowland finds that of 159 literary men, whose age at death was known, the average was as high as 69. Of 104 celebrated mathematicians cited by Frandini, eighteen lived to 80, and two reached the patriarchal age of 90 years.

A very important question in connection with cerebral softening, is its association with heart disease. Dr. Rowland enters minutely into this question, but does not furnish us with new facts. He agrees with Dr. Watson and Copland, that the heart disease, when co-existent with cerebral softening, should be regarded as typical of a general alteration of the vascular system, probably of the nature of fatty degeneration.

The nature and pathology of cerebral softening is next reviewed, and, as the author remarks, "with no little hesitation, as it is full of intricate questions, on which the most accomplished pathologists still hold opposite opinions." In reference to the nature of this lesion, too much stress has, in the author's opinion, been laid upon colour. Redness has been looked upon as evidence of its inflammatory origin, without reflection that this appearance may depend upon simple congestion, or even imbibition. Dr. Rowland thinks that the colour is often secondary to the softening.

The colourless softening, to which the term *white* softening has been applied, has also been misinterpreted, as the author shows.

Yellow softening, according to Rokitanski, occurs under the several circumstances following:—1. It encircles a spot of inflammation. 2. It appears in the neighbourhood of the ventricles in acute hydrocephalus. 3. Around apoplectic extravasations.

Of all the opinions as to the proximate cause of these varieties of softening, that of their inflammatory origin is the most general. The author quotes several writers who hold these views, making particular mention of Dr. Hughes Bennet, who, with Gluge, detected the presence

of exudation corpuscles, which were considered as conclusive of the nature of the cases in which they were present. These were commonly seen in the red softening, but less frequently in the white variety. The latter is, according to the author, either the result of fatty degeneration, or it may be the result of obstruction of the vessels leading to the part. The occasional effect of a ligature on the carotid artery is well known, and marked examples have been recorded by various writers.

The diagnosis of softening of the brain from sanguineous apoplexy, is one of the most important questions connected with the disease, and is so regarded by the author. In apoplexy the attack is generally without warning; in twenty cases in which a clot was found after death it was so. In twenty cases of softening the comatose seizure was without precursory symptoms only in two. In sixteen out of the remaining eighteen, headache was a prominent symptom; and in twelve paralysis preceded coma. When, therefore, the attack is quite sudden, the probability is that it is apoplexy. Coma of a transitory nature, frequently repeated, is characteristic of softening. The diagnosis of the two forms of softening is chiefly to be made out by the age and general appearance of the patient.

Dr. Rowland concludes his treatise with the treatment of cerebral softening in its various forms. On this subject his remarks are eminently judicious. The impending danger is earnestly to be averted by complete relaxation from intellectual exertion, and the withdrawal from exciting subjects of thought. All the functions are to be maintained, as far as possible, in a state of regularity. In the actual disease much discrimination is required in the choice of remedies; and here discrimination is necessary as to the form. In the inflammatory variety general bleeding may sometimes be advisable, but the author is more generally in favour of topical bleeding, counter-irritation, and purging. In many cases a stimulating plan will be required, and quinine, ammonia, and wine will be suitable. In the confirmed disease his chief confidence is in small doses of the bichloride of mercury. His experience is adverse to the use of strychnine.

We here close Dr. Rowland's volume, and in doing so give our cordial assent to its value; but of this we have no doubt many of our readers will convince themselves.

Proceedings of Societies.

BATH AND BRISTOL BRANCH.

At the Quarterly Meeting of the BATH AND BRISTOL BRANCH, held at the Royal Western Hotel, Bristol, on December 17th, at eight P.M., there were present—Dr. SYMONDS, in the chair; Drs. Budd, Davies, Edwards, J. C. Fox, F. K. Fox, Swayne, Trotman, and Tunstall, Messrs. Allen, Bartrum, Barrett, Burroughs, Colthurst, Cox, Clark, Crang, Church, Collins, George, Hamilton, King, Lancaster, Mayor, Norman, Ogilvie, Ormond, Prichard, Player, J. Soden, Sawyer, and Skeate.

The minutes of the last quarterly meeting in Bath having been read and approved, Dr. C. EDWARDS read his paper entitled "Chloroform and its Uses," which called forth sundry remarks from Messrs. Barrett, King, Norman, Colthurst, Lancaster, Drs. Tunstall, Swayne, and Symonds, the last of whom had used it with considerable advantage in a case of severe dyspnoea dependent upon an enlarged heart, with violent spasmodic action, but without mechanical obstructions. He mentioned it as being one of those diseases which was usually considered to forbid its use.

Dr. SWAYNE gave some valuable statistical observations on the different kinds of cranial presentation.

Mr. BARRETT then occupied much time in detailing from his note-book, with a running commentary on the treatment of two cases, which he had, during his attendance upon them, diagnosed as colic, but which *post-mortem* examination showed to be internal strangulation of the ileum.

Mr. J. SODEN then narrated in a very concise but admirable manner, a case which he had attended with Mr. Gore, in which, from the obstinate constipation, accompanied by fecal vomiting, internal strangulation was suspected, but which ultimately recovered.

Mr. CLARK exhibited a young man upon whom he had performed Dupuytren's operation for artificial anus, caused by sloughing of a strangulated hernia [The history of this exceedingly rare and interesting case will be published.]

Dr. Budd also exhibited some beautiful pathological specimens, but owing to the lateness of the hour was unable to read their histories.

[Of the above papers, Dr. Swayne's has been received, and the respective authors of the others have kindly intimated their intention to forward them. The whole will be published as early as possible in future numbers of the *Journal*.]

MIDLAND BRANCH.

THE first Quarterly Meeting of the MIDLAND BRANCH of the the Provincial Medical and Surgical Association, was held at the Town Hall, Derby, on

Thursday, December 4th, the President, Dr. BENT, in the Chair.

The rules for the government of the Midland Branch having been read by the Secretary, and the attention of the meeting having been called to the resolutions of the first meeting, it was

Proposed by Mr. FOX, seconded by Mr. W. JOHNSON, and carried unanimously,—“That Dr. WILLIAMS of Nottingham, be the President-Elect.”

Proposed by Dr. JOHNSON, seconded by Mr. GREAVES,—“That Mr. DARBY be the Honorary Secretary for Nottingham.”

It was resolved that the next Quarterly Meeting be held on the first Thursday in March, at three o'clock, in the room of the Derby Philosophical Society.

The foregoing preliminary business having been gone through, an excellent paper on "Epilepsy" was next read by Dr. HITCHMAN, the talented superintendent of the Derby County Lunatic Asylum, for which the cordial thanks of the meeting were voted on the proposition of Dr. HEYGATE, seconded by Mr. Fox. [Dr. Hitchman, on the suggestion of the members, kindly consented to allow the publication of the paper in the *Journal* of the Association.]

Mr. JONES, of Derby, read an interesting paper "On Prolapsus Uteri," and introduced to the notice of the members a new abdominal support, which he has found of great service in the treatment of the cases to which his essay referred.

Mr. CANTRILL of Wirksworth, requested the attention of the meeting to the Rules of the Manchester Medico-Ethical Association, and urged upon the members the desirableness of adopting and incorporating them with the general rules of the Midland Branch. His proposition met with hearty approval, and it was left to the committee to consider in what way Mr. Cantrill's suggestion could best be carried out.

NORWICH PATHOLOGICAL SOCIETY.

At a meeting of the Society, held December 18th, 1851, Dr. CROWFOOT, of Beccles, President, the following resolutions were carried:—

1. That the members of this Society consider the system of treating diseases which has been called homoeopathy to be founded on false data, and propagated through the combined influences of ignorance and imposture. That they, therefore, believe the associating with homoeopathic practitioners to be degrading to science and dishonourable in a moral point of view; and pledge themselves on no account, knowingly, to meet such practitioners in consultation.

2. That this meeting sees with disapprobation, that the College of Surgeons remain apathetic in the matter of homoeopathy and the other systems of quackery that are prevalent in the present day.

3. That the above resolutions be published in the *Provincial Medical and Surgical Journal*, the *Lancet*, and the *Medical Gazette*.

EPIDEMIOLOGICAL SOCIETY.

At a meeting of the Society, held on Monday, December 1st, 1851, at the house of the Royal Medical and Chirurgical Society, Dr. Babington in the chair,

Dr. MILROY read a paper "On the Circumstances Connected with the Rise and Development of the Asiatic Cholera in the Island of Jamaica." After taking a brief retrospect of the course and duration of the pestilence in the New World, upon its first visitation in 1832, and shewing that it then exhibited a tendency to cling with greater tenacity to certain regions there than to any countries of Europe, the author gave an account of its progress in the United States, Canada, the Gulf of Mexico, and the Island of Cuba, in 1849 and 1850, until it appeared in Jamaica in the beginning of October of the latter year. It is a curious fact that fourteen months previously several very suspicious cases occurred at Port Royal and Kingston, so that apprehensions were then entertained that cholera had fairly made its appearance in the island. At that time Dr. Ferguson, the leading medical practitioner in Kingston, addressed a letter to the Mayor on the necessity of taking immediate steps, in the way of preparation, against the impending outbreak. His remonstrances were unheeded, and nothing was done. During this year, also, there was a peculiar disease, somewhat like to the potato blight, among some of the esculent roots of the island. The weather in 1850, more especially after the month of May, was remarked in every part of Jamaica to be unusually wet and extremely hot, with a close stagnant condition of the atmosphere, and a frequent absence, for days together, of the accustomed sea breeze. There was also a low state of the barometer. Besides these atmospheric peculiarities, there was a very remarkable rise in the tides;—a circumstance which, taken in connection with the oppressive state of the weather, was believed to prognosticate the advent of a dreadful hurricane, or, it might be, of an earthquake, from both of which disasters Jamaica has suffered most severely upon several occasions. The medical men very generally anticipated a sickly autumn, the season being much like what it had been in some former years, when malignant fevers prevailed epidemically. On the 7th of October the first case of cholera at Port Royal occurred in a woman, 50 years of age, living in a small filthy house near the beach. She had had an attack of bowel complaint a month or six weeks before, and had just recovered from it when she was seized. The case proved rapidly fatal, and was quickly followed by other cases in the same yard, and subsequently in every part of this most filthy and unwholesome seaport town. In less than a month about one-third of the population were swept away.

It is worthy of notice that, ten days previously to the occurrence of the first case at Port Royal, a woman had died on the opposite side of the island, after an illness of about sixteen hours, with almost all the symptoms of malignant cholera. The exact nature of the case is uncertain, from the patient not having been

seen by any medical man. No other cases occurred at the time, either among the woman's family or in the neighbourhood. She had been nursing another woman affected with bowel complaint, and had been much exposed to the chill night-air immediately previous to being attacked.

From Port Royal the pestilence rapidly extended to Kingston, about six or seven miles up the harbour, Spanish Town, and other parts of the island. It is believed that at least 25,000 persons have perished out of a population of between 300,000 and 400,000.

Without entering upon any account of the disease in the island generally, Dr. Milroy, upon the present occasion, confined himself to giving a narrative of all the circumstances connected with the occurrence of the first case at Port Royal, with the view of determining whether there exist grounds for believing, as many have done, that the disease was traceable to importation by vessels from an infected port. He gave a summary of all the evidence upon the subject, and quoted the opinions of Deputy-Inspector of Fleets, Dr. Johnston, Mr. Watson, Surgeon of the Royal Naval Hospital, and of Dr. Walshe, R.A., and Deputy-Health Officer of the Port—the only resident medical man upon the spot at the date of the occurrence—all of whom agreed that it could not be so traced. He expressed his own conviction, founded upon a careful examination on the spot of the evidence on the case, coupled with a personal inspection of the locality where the disease first manifested itself, that this conclusion was just, and that to assert otherwise was to hazard a mere conjecture and groundless speculation.

The paper was closed with one or two medico-geographical remarks.

By looking at a map of the New World, it will be observed that the only Islands of the West Indies which have as yet been invaded by the cholera—Cuba and Jamaica—are the two which are situated the farthest to the west, and the nearest to the shores of the Gulf of Mexico, many points on which have, at different times, been severely visited. In the first epidemic, Cuba, the most westerly of all the islands, was the only one which suffered. In the second epidemic, it was invaded long before the disease appeared in Jamaica, although there was pretty frequent unrestricted communication between them all the time. As yet, all the other West India Islands have escaped. That this immunity has not been owing to non-communication with infected places, or, to the adoption of any vigorous quarantine, is perfectly well known. Everything in the history of the epidemic seems to indicate that its migrations may occur independently of human intercourse, and in spite of any barrier which man has sought to oppose to them. It may be difficult to account for them; but much of the difficulty may arise from the want of accurate data to enable us to follow its course with exactitude; that there are currents and moving powers in the atmospheric ocean, above and around us, which we have hitherto failed to appreciate, is probable from many considerations; nor does it seem unreasonable to believe that by following the example of Colonel

Reid in working out his theory of storms, viz., by collecting together a multitude of authentic facts as to the exact time and date of their outbreaks at different places on the world's surface, we may succeed in shewing that the manifestation and course of those noxious agencies, which give rise to blights in the vegetable world, and to epidemic and epizootic diseases in the animal, are not so capricious and accidental as they now appear, and as we, in our ignorance, often assume them to be.

Mr. R. D. Grainger, Dr. James Bird, Dr. Snow, and others, took part in the discussion.

The PRESIDENT announced that Mr. W. J. Cox would read his paper "On a rational mode of treatment of Cholera" at the meeting in January, 1852, and should time permit, a paper would also be read by Dr. BRYSON "On the Epidemic Prevalence of Dysentery in China, during 1841-2-3."

Foreign Department.

FRANCE.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

THE question debated some months since by M. Grisolle, as to the "*Influence of Pregnancy, Labour, and Nursing, on the progress of Phthisis*," has again been brought forward by M. DUBRUILH, in a memoir upon which M. Grisolle was called upon to report. In this memoir M. Dubruilh confirms the conclusions of the reporter, that so far from being arrested by pregnancy, pulmonary phthisis is aggravated by it, and that delivery, on the other hand, sometimes postpones the fatal termination, if the disease have not too far advanced.

M. JOBERT DE LAMBALLE related "A Case of *Tracheotomy in Croup*," the only interest of which consisted in the employment of an instrument so constructed as to keep the lips of the wound open without the necessity for the introduction of a tube into the larynx.

"A Memoir on *Congenital Phymosis*," by Dr. HENRY, contains the following propositions:—1. Congenital phymosis gives rise to three series of morbid phenomena:—(a.) Those which appertain to the genital organs. The penis and testicles are ill developed; the mucous membrane of the glans is preternaturally sensitive; coition painful, emission incomplete, precipitate, and accompanied with perineal uneasiness. The genital impulse is either exaggerated, leading to masturbation, or it is more or less completely extinguished. It is a frequent cause of nocturnal emissions. (b.) The urinary symptoms; are a frequent desire to micturate, and pains in the penis, which may lead to the suspicion of calculus. (c.) Various disturbances of the nervous system; having a great analogy with those of the female who is labouring under displacement or other uterine disorder, such as low spirits, hysterical feelings,

&c. 2. Excision of the prepuce is the only method of removing the above-mentioned category of ailments.

M. DEVILLIERS also brought forward his "*Researches on the Acute Venereal Treatment of Pregnant Women*." He finds as the result of his experience, that pregnant women bear the treatment well in the early months, unless their is great irritability of the mucous membranes, which would be intolerant of mercury under any other circumstances.

M. CHAMPOUILLON adduced some statistical evidence to prove that the proposition to substitute *iodized oil* for *cod-liver oil*, is not to be encouraged. He showed by figures, that while the value of the latter in scrofulous affections is of the highest order, such diseases were unaffected, or decidedly retrograded, when treated by the artificial substitute.

A case of "*Ligature of the Carotid Artery for Carotid Aneurism*," was detailed by Dr. LA CHAPEL, in which softening of the brain was the consequence of the sudden interruption in the cerebral circulation.

Another *new* mode of replacing a retroverted uterus was described by M. FAVROT. It consists of an India-rubber bag, which is introduced into the rectum behind the uterus, and then is to be inflated. The reposition of the womb is said to be thus readily accomplished.

ACADEMIE DES SCIENCES.

ONE of the most interesting papers lately presented to this Assembly, is that by M. REYNOSO "*On the Origin of Sugar in the Urine*." The author remarked in the first place, that the medulla oblongata was generally admitted to be the central organ which regulates the respiratory movements; and, moreover, that according to M. Flourens, a small spot just below the origin of the eighth pair is the veritable seat of respiratory function. It is also known that M. Bernard, by puncturing this portion of the nervous system in rabbits, caused the appearance of sugar in the urine, and he explains the phenomenon by saying that under the irritation thus produced, the liver secretes so much sugar that it cannot be burned off in respiration, and thus passes off by the kidney. The author, on the contrary, wishes to prove that the puncture of the medulla causes incomplete paralysis of the respiratory function, and thus that the sugar, normally produced in the system, no longer undergoes combustion. In support of this theory he states that sugar appeared in the urine in two patients who had been etherized, and also in animals strangled or drowned. He thinks that he thus establishes a direct relation between respiration, nervous influence, and saccharine urine.

[We are, we believe, still far from arriving at a correct theory of diabetes, if the mere non-combustion of the saccharine principle in the lungs be the *fons et origo mali*, the urine should be saccharine in all diseases in which the activity of the respiratory function is diminished, as in phthisis, hydro-thorax, &c. Such, however is not the fact. Although diabetes and phthisis are frequently associated, the pulmonary lesion is in our experience always secondary.—ED. P. J.]

An useful communication "On the Treatment of the Toxic Effects of Chloroform by Electricity," was made by M. Abeille, in which the author stated that he had ascertained experimentally, that no other measures were so effectual in restoring animation in asphyxia from the use of anæsthetic vapours.

Anomalous Case of Vicarious Menstruation.

Dr. Lecomte, of Eu, in France, has published, in *L'Union Médicale*, a case of an extraordinary description, of which we shall offer a short outline. The subject is a servant-girl, twenty-nine years of age, of apparently good health; she had never menstruated, and for the last seven years had experienced flushings and heat in the face, these symptoms recurring every four or five weeks. At these periods she likewise complained of severe lancinating pain in the right thigh, and sometimes in the leg and foot, the whole leg then becoming extremely tender to the touch.

Towards June, 1842, these phenomena increased in intensity, the patient became very weak, the abdomen felt tense, tympanitic, and tender, and she could no longer pass urine. Dr. Lecomte prescribed leeches to the hypogastrium, and prolonged hip-baths. The urine flowed a little; but at last the girl was persuaded to submit to the catheter, and a large quantity of dull and foetid urine was drawn off.

Now began a series of strange phenomena. The bladder, uterus, stomach, and rectum began to throw off what the patient called *balls*; these were pieces of membrane, or rather membranous casts, white, dense, and covered on one side with gelatinous matter. The vesical casts were somewhat large, as she was obliged to extract them with her fingers. On a former examination the internal organs of generation could hardly be properly explored, as the hymen was unbroken and rather tense, but the casts now came per vaginam, and the patient being obliged to dilate the parts herself, in order to give passage to the membranous formations, it was found on examination that the os was pervious, and the cervix of the normal size, though tilted backwards. Here the casts assumed a tubular shape.

The stomach now became very irritable, and a great abundance of glairy matter, mixed with pseudo-membranes, was thrown up. The vomiting now and then was of a purely sanguineous character, and in the coagula ejected an *ascaris lumbricoides* was noticed. The patient stated that she had likewise seen such parasites in the matters which had been expelled from the vagina. Diarrhoea supervened a little time afterwards, and in the dejections the same pseudo-membranous products were observed.

After a few weeks' respite, the symptoms recurred with renewed intensity; all the above-named organs secreted the same membranous products, but the uterus was evidently the most active. In one day Dr. Lecomte extracted ten casts, of a red colour, from the vagina; they were rolled up, and exhibited now for the first time. One of these presented on one side an infundibular shape, which made the medical attendant suspect that the membrane must have been formed in close vicinity to the fallopian tube.

The ejection of the casts was always accompanied by much pain, the latter being sometimes so intense as to cause the patient, who was far from being pusillanimous, to roll about in the bed with agony. The sanguineous flux was now suddenly transferred to the ears; these organs discharged each about a tumblerful of blood; vomiting of the same fluid came on a few days afterwards, and the casts were again ejected from the stomach, intestines, bladder, and uterus. When these symptoms had ceased a great improvement was noticed; the patient gradually became stronger, and from 1842 to the present time, the girl has experienced no uneasiness but dysuria every two or three months, except in July, 1843, when the most complete relapse occurred. The author does not say whether any amount of regular menstruation has appeared since the casts are no longer secreted. This is a great omission. The pseudo-membranous products were examined by M. Mialhe, and were found to be composed principally of albumen.

Remarks on Diseases of the Heart.

In the *Gazette Médicale de Strasbourg*, M. Forget has published some interesting comments on cardiac diseases. He enumerates two laws; the first, that dilatation of a cavity always occurs behind the obstruction, and contraction of the cavity, on the contrary, takes place before it. Thus obstructive disease of the aortic valves induces dilatation of the left ventricle, while contracted mitral, existing alone, induces what is called concentric hypertrophy of the same cavity. When both valves are contracted, the lesion of the ventricle will correspond with the relative degrees of obstruction in the two valves. It is not, however, absolutely necessary that valvular disease should be present to induce these changes. The ventricle will dilate if it discharges itself less readily than it fills, and it will diminish if it receives less than a normal quantity of blood.

M. Forget has ingeniously applied these facts to diagnosis. When one valve only is obstructed, it is easy to recognise it by the seat and qualities of the bruit; but when both valves is diseased, the information derived from the sounds is insufficient. It is then, he says, that the value of the above knowledge is found. "If there is narrowing of both aortic and mitral valves, the greatest amount of obstruction may be known to be at one or the other, accordingly as the ventricle is, or is not dilated."

M. Forget shows, further, that a knowledge of these circumstances is not a mere matter of scientific curiosity, but has also a real bearing on practice.

New Mode of Removing Uterine Polypi.

M. Gensoul (*Gazette Médicale de Lyons*) has recommended the use of strong forceps for the removal of uterine polypi. Taking the opportunity of the menstrual period, when the uterus is both lower down and more patulous, he introduces a pair of forceps, such as are used for nasal polypi, and encircling the pedicle in the gripe of the blades, he ties the handles, and leaves the instrument to drop off spontaneously.

[This plan may succeed very well in small tumours, but in those of larger size it is not likely to surpass the

ligature and Gooch's cannula, inasmuch as with a broad pedicle strangulation cannot be obtained by it with certainty.]

GERMANY.

Obstetrical Hints.—By Dr. ALBERS.

The *Neue Zeitschrift für Geburtskunde*, vol. 24, among other interesting original papers, contains some practical observations by the above writer, from which we make a few selections.

Treatment of Uterine Hæmorrhage.—The author advises a concentrated solution of the muriate of iron as an injection, and applied by means of a sponge plug, saturated with it. If an injection is used, it should be tepid.

Impaction of the Head Between the Third and Fourth Positions.—It sometimes happens that the head becomes engaged at the brim, the occiput descending in front of the promontory of the sacrum, while the root of the nose is fixed behind the symphysis pubes. No force can move it, and the blades of the forceps slip, and cannot be satisfactorily applied. The author has known several instances when in this dilemma the practitioner has had recourse to perforation, although the pelvis has been well formed. The right practice is to apply the forceps, not with the endeavour to extract, but to turn the head into the third position. It should then be left to nature; and in most cases delivery will be speedily accomplished.

Ossification of the Uterus.—Two or three cases are on record in which a portion of the uterus has been converted into bony matter; but so extensive an example as the following (*Medizinisches Correspond. Blutt de Wurtemberg*) must be looked upon as unique:—A woman, aged 72, died of ascites. On examination, in addition to some unimportant visceral lesions, the region of the uterus was found to be occupied by an osseous pyriform body, to which the broad ligaments and fallopian tubes were attached. The vaginal portion of the cervix was cartilaginous. On cutting the body open with a saw it was found to contain a cavity.

Oxalate of Potash in Puerperal Metritis.—Some remarks on the treatment of puerperal fever, by Dr. Welti, occur in the *Zeitschrift für Erfahrung Heilkunst*. The success of his treatment is shown in the fact (if credible) that of twenty-five cases he has only lost one, while before he adopted his present treatment he lost one in three. The dose of oxalate of potash is a grain every hour, with one grain of extract of hyoscyamus in solution.

Dr. Welti classifies puerperal fever cases under three heads, according to its form. The first is a mild, the second an obstinate form, requiring larger doses, or the combination of some other treatment. The third is metritis already existing before confinement, and becoming decided as soon as delivery takes place. Metritis occurs mostly three days after delivery, whether this has been natural or instrumental, and either comes on stealthily or in a decided and acute form. Yet sometimes it makes its first appearance fourteen days, or three or four weeks, after delivery.

The first of these forms is the most important, and admits of the most speedy relief. The author's practice supplied him with three cases. The first, in 1830

under the old treatment, died. The other two, in 1837, were cured in four days. All were easy cases of labour, requiring assistance, the first turning, the two others the forceps. In these cases the uterus, already in a morbid state, had lost its contractile power, and felt very hot to the hand, when introduced into it to remove the placenta, on account of hæmorrhage. He did not employ the oxalate of potash alone, but gave it in large doses along with some nitre, and calomel, and opium.

The second milder form of puerperal fever is that which occurs from one to three days after delivery, and is more frequent after natural than artificial labours. The author gives one case of this (fatal) where the patient remained in *statu quo* under the treatment with oxalate of potash; but the friends being alarmed, another practitioner was called in consultation, who had recourse to bleeding, leeching, calomel, &c. Dr. Welti predicted that the patient would die, and the patient died accordingly.

The third, and often from its complications, most troublesome form of metritis, is that which occurs three or four weeks after delivery. Dr. Welti narrates two cases of this kind, which occurred during intensely hot weather in June, 1849. In the first case all went on well till the 15th day, when hæmorrhage came on suddenly, for which acids and ergot of rye were prescribed. The bleeding was arrested, and the patient kept well till the twenty-second day, when it recurred; the same treatment was ordered, but without good results. On this same day the doctor was called to see the patient immediately. He found her sick, the hæmorrhage abated, but the uterus as large as in the fourth month of pregnancy, and tender; the pulse quick and full. The breast and arms covered with purple spots; the right leg had for four days been swollen and painful. The thirst was urgent, and the abdomen distended and tympanic on percussion. The patient stated that since the hæmorrhage had been checked eight days previously, the pains in the pelvic region had been constantly occurring from time to time, and the uterus gradually enlarging in size. Nothing was ordered at the moment. The patient was seen again in two hours, and the disease had by this time made astounding progress: the uterus was as large as in the fifth month, the belly distended to a marked degree, and the thirst and quickness of pulse increased. The swollen leg was treated by camomile fomentations; and Dr. W., regarding the metritis as the radical ailment, ordered gr. x. of extract of hyoscyamus, ser. j. of oxalate of potash, dr. ss. of nitre, oz. j. of syrup, and oz. iv. *aqua cerasorum*,—a table-spoonful for a dose; the two first doses to be given at half-hourly, and the rest at hourly intervals. The first dose was refreshing to her; from the second she obtained more relief; and after the third the pains ceased, and she steadily improved. She fell asleep at midnight, and was in an improving condition in the morning. The medicine was continued during next day, at longer intervals; and in ten days all the symptoms had disappeared under this simple treatment, without bleeding or leeching, or other means.

Dr. Welti narrates another similar case occurring during the third week, where a like result followed a similar treatment. He had also cured two diseases of metritis, occurring twelve hours after delivery by turn-

ing, with no other remedy than the above mixture.—*Monthly Journal*, October, 1851.

Liniment of Nitrate of Silver in Burns.

Dr. Kalt informs us, (*Schmidt's Jahr.*, 1851,) that he has derived great advantages in extensive superficial burns, from the following liniment:—Nitrate of silver, *dr. iij.*; distilled water, *q. s.*; linseed oil, *o.j.*

General Retrospect.

PRACTICAL MEDICINE.

Peculiar Appearance of the Tongue in Malarial Diseases.—By Dr. OSBORNE.

The author states that his attention has long been directed to a peculiar condition in the tongue of patients labouring under miasmatic diseases. It is an essential departure from the normal aspect of the edge, constituting a distinct lateral boundary of the tongue, occupying more or less surface, according to the charge of infection in the system. Ordinarily the colour amounts only to a very faint bluish tinge, which is liable to be lost, or merged in the various tints imparted to the tongue by various diseases. The most fixed condition of this symptom is an appearance of indentation or crimpling transversely, which is apparently confined to the subjacent tissue, while the superficial tegument is moist, smooth, and transparent. In a word, it seems to be a continuation or encroachment of the inferior surface upon the superior and lateral borders of the tongue, greater as we approach the root of that organ.

The author states that the fidelity of this symptom to the source of its origin is, under all circumstances, fully equal to the importance he has attached to it. In a considerable number of cases of the different forms of dropsy, neuralgia, and inflammation, it has alone enabled him to reach a correct diagnosis, when every other symptom seemed to deny the agency of malaria in the case. Wherever seen, he has invariably assumed that there existed a tendency to intermittent disease, and upon watching the progress of the case, have as invariably detected this condition. In numerous cases of pulmonary inflammation, where the fever seemed continued, the cough unabated, the oppressive restoration persistent, and the pulse unvarying in its activity, the physical signs have designated with great accuracy the periods of repose and excitement in the course of the disease. In the gastric and intestinal phlogoses, again, whether as causes or consequences of fever, if this peculiar impression is seen upon the tongue he boldly states that no apprehension need be felt in the administration of quinine, however malignant the case may appear. Here also intermission, varying in degree according to the severity of the disease, is always present, and, generally speaking, the shorter the period of repose the greater the quantity of medicine required, and *vice versa*. He has not hesitated, in many cases, where the disease was marching rapidly to a fatal termination, to prescribe one, two, and even three

drachms of sulphate of quinine at a dose, to be repeated according to the urgency of the indications.—*Western Journal*, (U.S.,) August, 1851.

Case of Aneurism of the Heart.—By Dr. RENAUD.

A well-marked instance of this rare form of aneurism has been placed on record by Dr. Renaud, occurring in the person of a female who died suddenly while quarrelling, under the influence of liquor. The description of the heart and appendages is as follows:—The pericardial surfaces were firmly adherent. The heart appeared larger than usual, and somewhat irregular in its outline. The left ventricle was hypertrophied, and at its apex there was a rounded opening, through which a small bullet would pass. This communicated with an aneurismal tumour, capable of containing from three to four ounces of fluid. With the exception of a little jelly-like coagulum, the sac was empty. The opening through the ventricle was well rounded, and had a tendinous-looking margin. The aneurismal sac was dense in texture, and upwards of two lines in thickness at the upper part nearest the ventricle, where the muscular fibres of the heart were partially expanded on its inner surface. The valves of the heart and coats of the arteries were healthy, and but little blood was found in the heart.—*Medical Gazette*, Oct. 31, 1851.

Cases in which there was unusual Difficulty in the Diagnosis of Pleuritic Effusions.—By T. A. BARKER, M.D.

The first case related by the author was one in which there was extensive emphysema of the left lung, which had encroached greatly on the right side of the chest, pushing the heart and mediastinum beyond the mesial line. The right lung, which was closely adherent to the costal pleura, was reduced to about a fourth of its usual size, was exsanguine, and contained no air, resembling a lung compressed by effusion in the pleura. In consequence of these changes, no respiration could be heard in the right lung during life: the right side of the chest was universally dull on percussion, and the patient could only lie on the right side or sit erect. Along with these symptoms were others closely resembling those which usually attend hydrothorax; and the dyspnoea and symptoms of approaching apnoea being very urgent, the author thought himself justified in having a very fine trocar introduced into the chest, in order to ascertain positively whether there was fluid. No inconvenience resulted from the operation, and the symptoms were soon afterwards explained by the discovery, on *post-mortem* examination, of the very unusual state of parts above described.

The next case was one in which, without any of the general symptoms of pleuritic effusion, it was discovered, by auscultation, &c., that there was no respiration going on in the posterior third of the left lung. In four days the person died. The lungs were healthy; but there was extensive effusion, confined to the back part of the chest by a very narrow line of adhesion, extending from the upper and back part of the chest to the diaphragm, half way between the ribs and the sternum. The author referred to three other cases

which he had seen, in which the pleuritic effusion had been limited by adhesions in the same position, and precisely similar; only one of these had been seen by him during life, and in that the symptoms closely resembled those in the case last related. Two other cases were shortly alluded to, in which there was emphysema to a considerable extent; but respiratory sounds could be heard in every part of the affected sides, in consequence of the lung being kept partially in contact with the ribs by mucous adhesions, forming several separate cavities in which the purulent matter was contained.—*Medico-Chirurgical Transactions*, 1851.

SURGERY.

Treatment of Varicocele by Gutta Percha Dissolved in Chloroform.—By H. G. CAREY, M.D., of Dayton, O.

After having used gutta percha considerably for other purposes, a knowledge of its properties forcibly suggested it in solution, as admirably fitted to fill the desired objects sought in the treatment of varicocele. In order to apply it, the patient is placed upon his back, and by means of cold the scrotum is corrugated until it is drawn firmly over the root of the penis, compressing the testes firmly in the upper portion of the inguinal pouches; then, by means of a camel's hair pencil, after the hair has been removed, apply the solution freely over the site of the scrotum, allowing it to extend on all sides some distance, by a thin attachment; but over the scrotum proper lay on a succession of coats, until a uniform covering throughout of a line in thickness is obtained, which will be sufficiently strong to form an artificial pouch of the nature and character desired. This thickness will be so yielding and pliable as not to afford the wearer any considerable inconvenience. Soon after the solution is applied to this sensitive part the patient will complain bitterly of the burning sensation experienced, depending upon the presence of the chloroform; but this temporary inconvenience will soon pass off. The constitutional indications, if there be any, must not, of course, be neglected.

The author has not as yet had an opportunity to test the powers of this article in relieving the same condition of the veins in the extremities, but thinks that much pain might be prevented, and success in the treatment greatly increased.—*Western Lancet*, (U.S.)

MIDWIFERY AND DISEASES OF CHILDREN.

A Successful Case of Parturition in a Patient who had previously undergone Ovariectomy by a Large Incision.—By JOHN CROUCH, M.R.C.S, Bruton, Somerset.

The following interesting communication was made at a recent meeting of the Medico-Chirurgical Society:—

The subject of this case was a healthy young woman, twenty-six years of age. Two years ago a multilocular ovarian cyst, weighing fourteen pounds, was removed by a long incision. Five weeks after the operation she walked a distance of five miles. During the next winter the catamenia appeared at regular intervals, and her health was good, except that she had an occasional pain

in the left groin, and a slight difficulty in micturition, sometimes followed and relieved by a muco-purulent discharge in the urine. In 1850 she married, and on the 9th of October last she was delivered of a male child, after a lingering labour. It had been feared that the expansive powers of the parietes of the abdomen would be impaired by so large a scar passing through their centre; but it was found that the skin dilated naturally, and that the cicatrix itself had increased in length three inches, and in breadth one-sixth of an inch, during the period of gestation. Seven weeks after the delivery the cicatrix in the abdomen had returned to the same dimensions as before the pregnancy—five inches and a half in length, and a quarter of an inch in breadth.—Reported in *Lancet*, December 6, 1851.

Memoranda in Infantile Therapeutics.—By Dr. EDWARD WILLIAMS, Dublin.

Dr. Williams calls attention to the following essential points in the treatment of infantile diseases:—1st. They bear blood-letting badly, with not unfrequently fatal results; much caution, therefore, is required, and the bleeding from leeches is difficult to check. 2nd. Tartar emetic prostrates them much more than adults, nor do they rally soon from its effects; the nervous system becomes partially paralyzed, and the injurious tendency of the medicine is shown on all the functions of the body. 3rdly, Opium is more or less a direct poison, causing not unfrequently congestion of the cerebral substance and an apoplectic tendency. 4th. Mercury never salivates the very young child. 5th. Blisters are apt to slough, and therefore should never be used in the first stage of acute inflammation where there is capillary engorgement and irritation, but rather in the sub-acute or chronic stage, where these vessels are stagnated and indolent, and where a stimulus is required to bring into healthy action these dormant vessels. 6th. The diagnosis of disease in children must naturally be difficult; they cannot, like adults, tell you of their sufferings; and the skill of the medical practitioner will be required to diagnose disease through indirect means. 7th. Mind not to go to the other extreme, and never bleed, never give tartar emetic, never give opium, never blister: remember, extremes are dangerous, *in medias res tutissimus ibis*. Sometimes you have two evils to choose between, viz.,—the injurious tendency of the disease if left unchecked by active treatment, and the probably injurious action of the treatment. Remember, one is a certainty, the other an uncertainty, and therefore you should choose the lesser evil.

In the first ten or twelve months of infant life, when it is supported entirely by the mother's milk, we should, if the infant suffers from ill-health, always make inquiries as to the state of the health of the mother; for feeding the child with other milk, either artificial or human (that of a nurse), will nearly always, in these cases, effect a cure without the assistance of medicine, the child here suffering through the mother.

Of course infants require smaller doses than adults. Where in one you would give an ounce, in the other, a year or two old, you would give a drachm.

But the greatest skill is to discover the seat of the disease, for they cannot tell you; and here I refer you

to Dr. Maunsell and Evanson's work on the "Diseases of Children." At page 105 they beautifully describe the means of diagnosis of disease in the three great cavities of the body—head, chest, and abdomen. "Three principal indications of physiognomy present themselves," say the authors, "connecting a particular set of features with one of the three great cavities, as we observed when speaking of the temperaments, and related in a similar manner. The expression of the upper part of the face, the forehead, eyes, and brows, indicating disease of the brain or nervous system; the features of the middle of the face, in particular the nose, being affected by morbid conditions of the organs of circulation or respiration; while abdominal affections are in a peculiar manner pointed out by the expression of the mouth or state of the lips."

When the brows are knit, the eyes fixed and staring, or looking wild or vacant, our attention is at once directed to the head; we observe whether the child puts its hand to its head, as in health infants seldom raise the hand above the mouth; next examine the pupils, and whether the limbs are rigid; these and other symptoms are evidences of disease of the brain.

Disease of the chest is more apparent, and the diagnosis easier; the ear will do much, assisted by the eye, and other symptoms.

In disease of the abdomen the lips are retracted or drawn, so as to show the teeth or gums; the countenance pale, sallow, or sunk; the child lies on its back with its knees bent or drawn up, and is pained by pressure on the abdomen; diarrhoea constantly attends, the stools being generally thin, green, or dark brown and foetid; there is much wasting; great thirst, particularly craving for cold water, and other symptoms. Teething commences in children about six months after birth, when there is sympathetic irritation in various parts of the body, which is more easily relieved by lancing the gums, thus easing the pressure of the tooth, the cause also being removed, than by giving medicines, which only palliate for a time, the primary cause of the ailments still remaining.—*Lancet*, Nov. 29, 1851.

Correspondence.

TWIN PREGNANCIES.

To the Editors of the *Provincial Medical and Surgical Journal*.

GENTLEMEN,—In the *Lancet* (Nov. 1), at page 415, is a report of the frequent occurrence of twin pregnancy, under the care of Dr. Tyler Smith.

The report states, "We recently saw a patient in St. Mary's Hospital, the subject of puerperal mania, whose obstetric history was very interesting and remarkable. She was 34 years of age, was not the subject of pelvic deformity, and had had, in all, seven labours. In three of these she had given birth to twins," &c.

During an engagement with L. Owen Fox, Esq., of Broughton, Hampshire, which terminated this last summer, I attended a Mrs. Phillips, living at a solitary

dwelling in the outskirts of the Stockbridge Union. This poor woman was the wife of a labourer, and on three successive occasions gave birth to twins; these were her only pregnancies. Each time she suffered much from oedema of the abdomen and lower extremities, which retarded the progress of labour. In the first and third confinements the presentations were natural, in the second an arm presented; turning, of course, was necessary in the last-mentioned case.

I felt some anxiety to know the result of a fourth pregnancy; but unfortunately about the period of her last lying-in her husband received an injury from the wheel of a waggon passing over his abdomen, which caused his death.

I could not ascertain whether there was hereditary disposition in the family to plurality of births.

I have never seen recorded the fact of a woman having given birth to twins three times in succession. If this poor woman had not been deprived of her husband probably her fourth pregnancy might have proved of a similar abnormal character.

I am, Gentlemen,

Your obedient Servant,

November 3, 1851.

EDWIN BISHOP.

EXTRA-UTERINE FŒTATION, HÆMORRHAGE AND DEATH.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—I observe in your last number, at page 593, a case headed "Rupture of the Fallopian Tube," and recorded by Dr. Whitton, of Llangollen, that so nearly corresponds with one that fell under my own observation, that I am induced to send it to you. I did not see the patient during life, but was, by favour of my colleague, Mr. Braithwaite, present at the autopsy, which took place April 30, 1840.

The subject of these memoranda was a young woman, mother of four children, and understood to be at the time five weeks advanced in pregnancy. She was in good health up to the 25th, on which day, while in the act of preparing dinner, she first felt faint; this was accompanied by a pain in the belly and a feeling of alarm. Mr. Braithwaite was sent for, and found her pallid and exhausted, with a frequent and feeble pulse; having been put to bed, she rallied considerably the following day, but on the third, the faintness and pain, with some sickness, increased, and she sank whilst in a state of syncope.

Post mortem appearances.—Body generally blanched to the last degree. On laying open the cavity of the abdomen, it was found distended with fluid and clotted blood; there was no trace of inflammatory action. After a minute search we discovered the source of the hæmorrhage to be a ruptured ovum that had been arrested in its transit through one of the fallopian tubes, and had there acquired its proper bulk, and had so far passed through its early stages without prejudice from abnormal position; the torn surface had a fibrinous or placental appearance, and corresponded with the ovum itself, which was found among the coagula. But

not the least interesting fact was exhibited within the uterus itself, which was slightly enlarged; the decidua were there in perfection, and in a state according with the period of pregnancy, and thickly lined the entire organ, forming a bed softer than one of down, prepared and awaiting the entrance of an occupant, which was destined to perish on the way, and to cause the destruction of the parent as a consequence.

A beautiful instance this of the independent yet combined and synchronous action of remote parts to effect an important object. The uterus persisted in its own peculiar duty of preparation so long as the ovum itself retained vitality; yet, doubtless, had this patient lived longer, the absorbents of the uterus would quickly have entered on their duty of removing the decidua.

Your faithful Servant,

CHARLES LINGEN.

Hereford, November 7, 1851.

DR. COOPER'S ADDRESS IN MEDICINE.

To the Editors of the Provincial Medical and Surgical Journal.

GENTLEMEN,—In the recently-issued volume of the "Transactions" of the Provincial Medical and Surgical Association, I see a paper by Dr. Cooper, of Hull, which was read as the "Address in Medicine," on the occasion of the Eighteenth Anniversary Meeting, and in which he takes up a subject of considerable importance, namely, "the relations and affinities of diseases, and their complications." I have been much pleased with the care and labour which have been bestowed on Dr. Cooper's paper, but I must, (in justice to myself,) take exception to the remark, that hitherto there has been "no attempt made to trace the general affinities or connections of diseased actions." If he will do me the favour to turn to the *Lancet* for August 3rd, 1844, he will find the first of a series of papers on the subject. These papers were unfortunately printed in an imperfect form, much abridged from the author's original MS., and published at very long intervals; but this, not from any remissness on the part of the writer, but because the Editor of the *Lancet*, could not find space for them, and thought that articles which related to the treatment of disease would be more suitable to his readers.* These papers (Paper xix.) terminate with the following words:—"In concluding these essays on general pathology, I have to regret many imperfections, and some errors, which have arisen in the condensation of the matter for the pages of the *Lancet*. I have also to regret that arrangements have not permitted their publication in a more consecutive form. My object has been, as I stated at the commencement, 'to insist on the importance of a philosophical analysis of the morbid phenomena, with a view to a just estimation of the various elementary conditions of disease; and more especially to direct a proper attention to the laws of association, by which these conditions are united, and

to the modifications produced by their co-existence and complications.'"

It will be seen that in my essays I have attempted a more completely analytical and synthetical method of inquiry than that pursued by Dr. Cooper, (irrespective of physiological speculation) and, so far as I know, the method I have adopted, and which appears to me the most philosophical, is original with myself. I am glad to welcome Dr. Cooper as a writer in the same field, and beg to subscribe myself,

Gentlemen,

Your obedient Servant,

JAMES BOWER HARRISON.

Higher Broughton, Manchester,
Dec. 23, 1851.

TREATMENT OF THE INSANE.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—“Insanity does not admit of being defined. It is not in the power of any human being to embody within the limits of a definition all the peculiar and characteristic symptoms of human derangement.”

So writes Mr. Forbes Winslow, an authority on the subject, and though not exactly my authority, I recommend his observation to many who consider themselves complete masters of the subject, and who have not to learn, but to teach,—

“And we unwilling slaves must bow.”

In the *Medical Gazette* for October 31, 1851, I find that Dr. Monro has honoured me with slighting notice, and I request permission in this letter to handle his remarks; it is not my intention to be led into any controversy, but to clear my way I must refer to his observations. He is no very formidable critic, nor have I yet to bow to the chair in which he has so complacently placed himself. I call not for his sympathy, nor will his opinion, as now announced, induce me to deviate from my own. He writes well for the meridian of Spring Gardens. He would say something to me, and I would say something to him, viz:—"that the conviction of an enlightened age" has also produced many follies—none greater than what bear upon the subject of our respective papers.

Our views are altogether different upon the management of insanity; mine have reference only to the law, not to its agents, to them I will pay every tribute of respect; but if Dr. Monro has a conviction that the judgment of these "shepherds" is sometimes inaccurate, why refuse me the same supposition?

But why are there shepherds, and who are the sheep? Are private establishments not to be considered their own homes, and are the inmates and those who have their care to be continually subjected to surveillance, and to be treated as if their habitations were prone to evil, and their objects more the desire of gain, than the effects of good management—of cure, if possible; if not, of rendering their lives, as much as may be, pleasurable to them? It is a curious philosophy that decides nothing can be right but what its own opinion recommends, and it is my perfect astonishment that at the

* The second paper is omitted from the index, but will be found at page 633 Vol. I., 1844.

present day these sumptuary laws should be permitted in our code. I say again, the law is inquisitorial, and every domicile might be subjected to it.

Where the insanity of State government begins or ends, I know not, but I know pretty well with whom rest the advantages.

The law has now been in full operation for some years. Can any statistical account be published of patients whose cures have been prevented or delayed, or to whom this act has consequently been beneficial? Dr. Monro lays down four rules for more frequent supervision, and these be they:—

1.—Frequent visits are necessary to free the minds of patients of injurious anxiety.

Whatever may be the experience of Dr. Monro upon this point, it differs essentially from mine. A patient possessed with the delusion of being unjustly confined, will only consider the Commissioner as being in league with other parties, and so strengthen the delusion. The endeavour to obtain “unrestricted confidence” between physician and patient will much more tend to obviate this feeling.

2.—Frequent visits are necessary to free the mind of the proprietor in doubtful matters of discharge.

I have never had a doubt as to the proper course to be taken in such a case. There is no test so good as requesting a relation or an intimate friend to visit the object of such doubt, and to remain some days. I have derived much satisfaction from this mode of proceeding, and I affix the most value to the opinion thus gained. I am sorry I cannot compliment Dr. Monro upon the arguments he uses in support of his views. I shall leave them, however, where I found them.

3.—Frequent visits are wanted to settle matters of unavoidable disagreement between patients and their ordinary superintendents and advisers.

The whole arguments produced to support this position I have a right entirely to deny; and I believe they will be found contrary to experience.

4.—Frequent visitation is necessary to free the mind of the Commissioner of those inaccuracies of judgment which rare visitation engenders.

This may be an excellent argument for frequent visitation in the receptacles of crime, conviction, repentance; but it comes with a very bad grace from a member of the medical profession. What, are we to be trusted with management of all other diseases, and in this alone is our intellectual and moral sense to be hoodwinked? If insanity be a disease, pray let the proper medicine be employed, and do not seek for this out of its proper course.

To illustrate this a little. From the incidents belonging to life I have had some changes of matrons; some have married, others have sought and obtained higher advantages, their great recommendation being the education they had received. I never knew one who did not presume herself mistress of all her duties as soon as she stepped into the house. I never knew one who, in the course of a few weeks, did not complain of difficulties and of unexpected annoyances. These soon yielded as a greater knowledge and experience enlightened them; and not one has left me without sorrow on both parts, for I well knew I had another to educate. These persons all acknowledged it was some time before

they could understand the peculiarities and proper guidance of their patients; but the inference of the Legislature seems now to be, that experience is but a fallacious guide, and that the superintendence of the fourth order of the class neuroses, should be principally intrusted to those whose education and habits of life have given them very little practical illustration as to their modes of acting upon the human system; or how often false conceptions or theories may act most ruinously upon the interests of the individual and those of his family. I write from what I know, and from no specious deductions? I take my present leave of Dr. Monro, probably we may have to meet again. Writing as I do, and with the thorough conviction I am right, I accept his Virgilian quotation—

“In re cede malis, sed contra audentior ito,”

The spirit of Dr. Monro's paper appears best in its conclusion, and in many remarks I can concur; but I must protest against the proprietor of a private establishment being considered an inferior officer to a commissioner. Is not the profession of medicine the profession of a gentleman; and because Parliament may have insisted upon knowing whether my house is clean, according to a settled plan then arranged, am I to be degraded and presumed to follow a menial occupation. The House of Commons, by their enactments, certainly went near to lower the “status” of a resident proprietor, medical or otherwise; but the good sense of the House of Lords, principally, I believe, by the advice of the late Lord Shaftesbury, amended the bill. To elevate, not to depress, would have been the best means of inducing persons of respectability to engage in undertakings, arduous, painful, sometimes ungrateful. Now if I were to begin life again, with the competent knowledge I possess of the physiology and treatment of insanity, I should long hesitate before I entered into that branch of practice.

In none of my letters have I mentioned Mr. Perceval's name. The report I received was signed by many. He must be a sincere friend who sent him the extracts from your journal, to which he alludes. This Friend's Society insists upon opinions they have formed: why may I not oppose them, provided I do so with weapons proper for the encounter? I have particularized none, I have libelled none; the admission of my letters in your journal is a guarantee for this; and though for a time I may use an “anonyme,” it is more for the sake of convenience, than of refuge. I am not sore upon any point of position in which I am placed. I have written from honest conviction, and from a belief that an injurious tendency as to the management of the insane is prevailing, and is contradictory to sound views upon the subject. Surely Mr. Perceval, whose character I somewhat know, and its amiable traits, will acknowledge there can be “zeal without discretion,” and that much harm may be effected by an insane desire to do good. (*Vid. Art. Poet. Lin., 38, et seq.*)

But the opinions of those who have noticed my remarks are essentially different from my own. I consider insanity a disease that may be cured, relieved, or guided under the direction of experience, without theoretical or metaphysical reasonings or reiterated investigations entering into such process. The law seems to think it a variation of human nature, which

falls under its immediate care, and must therefore establish a corps of officers to sweep the rooms of the domicile, to cleanse the breasts of the proprietors, and to prevent fraud and injustice taking the place of natural affection, of social endearment, and of human sympathy.

Yours obediently,
E. B.

BRISTOL ROYAL INFIRMARY MEDICAL SOCIETY.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—My attention has been drawn to a letter in the last number of your valuable journal, referring to some observations I had lately made in an address delivered to the members of the Student Medico-Chirurgical Society annexed to the Bristol Royal Infirmary.

I then stated that I was not aware that Student Debating Societies, similar in character to the one established in Bristol, had yet been founded in the provinces. It appears, however, from your correspondent's letter that several meetings had been held of a Student Debating Society, in connexion with the Queen's College, Birmingham, before our Bristol Association had commenced its meetings.

I beg now to correct my error, and to assure your correspondent that I am truly glad to find that our Bristol Society does not stand alone.

The lively interest I take in the advancement of the medical student, and the strong feeling I entertain of the great advantage he may derive from these associations, in connexion with his hospital studies, would lead me to view with sincere satisfaction the general establishment of Debating Societies of this character; and I trust that the example held out by the students of Queen's College, Birmingham, may be universally followed in our provincial schools.

I am, Sir, your obedient servant,

JOHN HARRISON,

Senior-Surgeon to the Bristol Royal Infirmary.

December 17, 1851.

MEDICAL BENEVOLENT COLLEGE.

A MEETING of the profession was held in the Medical Institution, Liverpool, on Friday, November 28th, but owing to some mistake the report was not forwarded to us for insertion at the time. Through the kindness of Dr. Dickinson we are now enabled to lay before our readers the following extract from the *Liverpool Courier*:—

"A public meeting, confined in this instance to the medical profession, which was held in the Medical Institution, on Friday evening last, leads us to embrace the opportunity of bringing before our readers the constitution of this charity, and earnestly soliciting the co-operation of the public in its behalf. We seldom

speak in vain in advocating Christian benevolence, and if we would on this occasion speak warmly, it is because "the heart knoweth his own bitterness." But we would not permit ourselves to be led away by feeling in a matter which demands judgment. We would not magnify evils that good might come. We would speak soberly the words of simple truth.

"It is a marked feature of the day, that people are becoming more alive to the principles of co-operation in the extension of the blessings of charity, and the laying up in store some provision for the future. Life Assurance Societies, which are rapidly extending over the country, have stimulated another class of the community to the establishment of benefit societies. But there are cases of need, where, under peculiar circumstances, and from natural causes, these excellent institutions fail to meet the requirements of the necessitous. A Life Assurance Society, supposing the principal payable at death, or that an annuity is granted in old age, implies an ability on the part of the insured to meet the annual subscription. He is provident for his family in the one case; he guards himself to a certain extent against the reverse of fortune in the other. But in either he is required to furnish in money, depending in amount upon the question of probabilities, an equivalent to the sum paid by the society. This, then, does not come within the range of charity; it is a business transaction entirely, and to it our observations are intended to apply.

"But we come to an institution purely charitable—the *Medical Benevolent Fund*—represented by a committee of most respectable gentlemen, and identified with Mr. Newnham, of Farnham. The object of this excellent charity is, to provide to the utmost of their ability temporary relief in cases of extreme urgency. Of it, while we commend it warmly, we do not intend to say more than that the last report is before us, and the cases referred to as relieved during the past year are very touching.

"We come now to the special object of our remarks—the *Medical Benevolent College*. It was only in June last that this society was established; and at the meeting in this town on Friday the profession unanimously testified to its importance, and pledged themselves to support it to the utmost. Although exclusively professional in the distribution of its charity, it is general in the elements of its support. For this reason do we appeal earnestly to the public. It numbers among its office-bearers several of our peers, three of our bishops, besides clerical, medical, and lay members. Its respectability is stamped; its extension will depend upon a benevolent public; its utility will, under God's blessing, be felt by those sheltered below its roof; and in after years, when the children educated within its walls shall have entered upon the active business of their lives, its remembrance will be cherished, and blessings descend upon the benefactors.

"Shall we be forced to say an appeal in Liverpool has been in vain? In Liverpool, where the medical profession is periodically exposed to more than the usual dangers attending the cure of infectious and contagious diseases; and where several always fall victims when these epidemics break out?

"The scheme recommends itself to our judgment as

well as to our heart, and with this conviction do we stand forth as its warm advocates. Subscriptions will be received by Dr. Dickinson, the zealous secretary for this town; or by Robert Bickersteth, Esq., the President of the Local Association.

"As an object for charitable bequest this institution is peculiarly fitted. A happy reaction is likely before long to take place, and as formerly bequests were for the most part confined to the children of the lower classes, and in a few cases to those of tradesmen, so now it is confidently hoped that a far more desirable purpose will be served by the legacies of the benevolent. Few know the wretchedness of poverty so much as the educated; and in their case private feelings usually prevent the making known their sufferings. The northern metropolis, plethoric with its palaces for children, but poor in its hospitals for the sick or the decayed in worldly means, feels it to be an infliction whenever a testator wills his fortune in the former channel; and on a recent occasion spoke out through the press against the evil. But there has risen up in that city a strong desire liberally to endow a retreat for decayed gentlewomen, and we wish it all success. Let the rich look to this, and learn to act with wisdom in the making of their bequests. In London a similar desire has more recently been emphatically expressed in favour of literary men, and a noble 'Guild' will ere long extend its aid to the man of letters. Governesses' Institutions on similar principles, and retreats for the widows and children of the clergy, are likely soon to extend the comforts of a home and the blessings of religion to those for whom they are intended. Here we find the medical profession large in numbers, far from rich as a body, and liberal in gifts of benevolence beyond that of any other profession, the clerical not excepted, asking help for the endowment of a building such as that for which we plead. Let them not ask for naught."

Such an address as this, emanating from the general press of the great commercial town of Liverpool, must indeed be gratifying to the founder and well-wishers of this noble institution, as well as productive of the greatest good in forwarding the consummation of their object.

WITH the view of assisting this benevolent undertaking, the medical men of Bedford held a meeting on Wednesday evening, the 17th of December, and unanimously passed the following resolutions, viz. :—

1. That the establishment of an asylum for distressed medical men and their widows, and a school for the education of their sons, is an object worthy of the cordial support of the profession, and has strong claims on the sympathy of the public.

2. That the members of the medical profession in Bedford forming this meeting pledge themselves by all available means to assist the accomplishment of so desirable an object, and earnestly exhort their professional brethren and friends throughout the country to aid them in carrying it out.

3. That a local Committee be formed, consisting of the following gentlemen, for the purpose of co-operating with the Central Committee in London, and of receiving

subscriptions and donations from the profession and public, namely :—Isaac Hurst, Esq., R. Couchman, Esq., W. Thurnall, Esq., Dr. Dick, J. Harris, Esq., W. Bailey, Esq., C. Robinson, Esq., and Dr. Barker.

4. That Isaac Hurst, Esq., F.R.C.S., be requested to accept the office of Chairman, and Dr. Barker that of Honorary Secretary and Treasurer, to the Local Committee.

Several donations and subscriptions have already been promised in this town and neighbourhood.

Medical Intelligence.

ROYAL COLLEGE OF PHYSICIANS.

The following gentlemen were admitted members on Monday, December 22 :—Dr. Bishop, Albion Street, Hyde Park; Dr. Garrod, Hartley Street; Dr. Hassall, Park Street, Grosvenor Square; Dr. Wilks, Bethel Place, Camberwell.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 19th ult. :—John Crown Agnis, Harewood square, Regent's Park; Lewis Hitchin Archer, Southampton Row; John Breakey, Monaghan; Erlin Clarke, Worcester; George Mallet Coventry, Llanrwst, Denbighshire; Joseph Gibson Dowse, Manchester; Henry Greenway, Plymouth; Joseph James Harding, Newcastle-upon-Tyne; George Pishey Thompson Hill, Boston, Lincolnshire; Bernard Kavanagh, Limerick; Daniel O'Donovan, Limerick; Albert Daniel Smith, Nailsworth, Gloucestershire; Richard Wilkinson, Bradford, Yorkshire; John H. Wilson, Shrewsbury, Salop; John Hancock Wolstenholme, Bolton, Lancashire; William Talbot Young, Madras.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, December 18th, 1851 :—Henry Powell Bannister, London; Richard Evans, Devonport; Frederick B. Fulcher, Maidstone; Henry John Harrison, London; James M'Cann, Ireland; Robert Brockman Newhouse, Dover; Josiah Ramskill, Leeds; Albert Taylor, Newcastle-upon-Tyne.

The following gentlemen were also admitted on Wednesday, December 24th, 1851 :—Thomas William Craster, Newcastle-upon-Tyne; Iberson Izod, Birmingham; Thomas Henry Mayne, Barnstaple, near Devon; Frederick White Palmer, Island House, near Loughborough; Charles Pardey, Leeds; Charles Warden, Birmingham.

SUFFOLK ASYLUM.

The Visiting Justices of the Suffolk Asylum, with their Medical Officer, have transmitted a memorial to the Secretary of State on the subject of the removal of criminal lunatics from hospitals for the insane.

UNIVERSITY OF LONDON.

M.D. EXAMINATION. 1851.

First Division: Robert Growse, Guy's Hospital; Samuel Osborne Habershon, Guy's Hospital; William Bird Herapath, Bristol Medical School and London Hospital; John Braxton Hicks, Guy's Hospital; Chas. Bland Radcliffe, Leeds School of Medicine; Henry Hyde Salter, King's College.—*Second Division:* Arthur Hill Hassall, Royal College of Surgeons in Ireland; James Jones, Royal College of Surgeons in Ireland.

APPOINTMENTS.

John R. Grahamsley, M.D., of the University of Edinburgh, and Honorary Assistant-Physician of the Royal Edinburgh Asylum, Morningside, has been appointed Resident Medical Superintendent of the Worcester City and County Lunatic Asylum. There were 57 candidates for the appointment.

Dr. Chambers has been elected Physician to the Royal Free Hospital, Gray's Inn Road.

MORE ARSENIC POISONING.

At the Court of Assizes in France, Helen Jegado, a servant, was put upon her trial for seven murders by arsenic, in 1850. The evidence showed that, during her life, no less than forty-three persons had been poisoned by her, including several of her mistresses, masters, and fellow-servants. Her counsel pleaded insanity, but the jury gave no credit to such a monomania, and found her guilty. She was accordingly sentenced to be executed.

INOCULATION AND VACCINATION.

An interesting instance of the value of inoculation under certain circumstances, has just occurred among the Sac and Fox Indians. The small-pox, which is usually so fatal to the aboriginal race, and which sometimes sweeps off whole tribes at once, recently appeared in the Sac and Fox community, and there they were induced to diet, encamp together, and be inoculated with small-pox virus. Fifteen hundred, out of twenty-six hundred, submitted to the operation, and not one died that was not previously affected with the disease. About 110 have died before this measure was adopted. None took the disease who had been previously vaccinated.—*New York Medical Times.*

MIDLAND OBSERVATORY.

Mr. Henry Lawson, of Bath, has offered to transfer the whole of his valuable astronomical, meteorological, and optical apparatus, (cost £10,000,) together with a contribution of 1,000 guineas, to trustees, for the purpose of founding a Midland Observatory. The Town Council, before whom the subject was brought, had no power to vote money for the purpose; but a public subscription is likely to be set on foot.—*Medical Times.*

FREE CANCER HOSPITAL.

A widow lady residing in Berkshire, has offered fifty guineas, to be paid in March next, in aid of the funds of the Free Cancer Hospital, Cannon Row, Parliament Street, provided nineteen other similar sums be forthcoming at that time for the like charitable purpose. Communications to be addressed to the chairman, the Hon. Colonel Ogilvy, or the secretary, Mr. W. J. Cockerill, No. 1, Cannon Row, Westminster. We can hardly doubt that this most generous proposition will be rendered available, and that benevolent persons will be found to make up the required amount.—*Globe.*

OBITUARY.

December 21st, at Cokermonth, aged 27 years, Dr. Addison Byers.

At his residence, 5, Oriel Place, Cheltenham, Dr. James Arthur, aged 71.

BOOKS RECEIVED FOR REVIEW.

Neuralgia; its various Forms, Pathology, and Treatment. By C. Toogood Downing, M.D., M.R.C.S. (The Jacksonian Prize, 1851.) London: J. Churchill, pp. 375.

Monthly Journal of Medical Science, Dec., 1851.

London Journal of Medicine, Dec., 1851.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

Gentlemen will observe that the Annual Subscriptions become due on the First of January, those who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association, Worcester.

Members who wish to propose Associates are reminded, that as the subscription commenced on the first of January, it is the most convenient time to introduce new Associates.

It is also particularly requested that all post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

JAMES P. SHEPPARD, Secretary.

Worcester, January, 1852.

TO CORRESPONDENTS.

Communications have been received from Dr. Oke, Mr. Reid, Dr. Cormack, Mr. Harrison, Mr. Harvey, and the Manchester Medico-Ethical Society.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho. But all communications respecting the routine business of the Association should be forwarded to James P. Sheppard, Esq., the Secretary of the Association.

NOTES

ON THE

TREATMENT OF CURABLE DISEASES.*

By W. S. OKE, M.D.,

Extra-Licentiate of the Royal College of Physicians, Physician to the Royal South Hants Infirmary, &c.

OPHTHALMIA INFANTUM PURULENTA.

THIS kind of inflammation is communicated to the conjunctival membrane of the child by its coming in contact with specific discharge during the passage of the head through the vagina. It takes place soon after birth, and is easily subdued in the incipient stage; but if neglected, and the corneæ are involved, the worst consequences will ensue; indeed, it may truly be asserted that the vision will be as certainly preserved by early and judicious measures as it will be lost by procrastination. The palpebræ are inflamed, swollen, and closed; and upon being slightly compressed a considerable quantity of purulent matter will be discharged. In this case, as in strumous ophthalmia, very much will depend upon the manner in which the local remedies are applied.

Some competent attendant must be instructed to inject the lotion (1) betwixt the palpebræ and the globe of the eye twice a day, that it may be done effectually. After this the tarsi are to be lightly smeared with the ointment (2); folds of linen, made wet with saturnine wash, are to be constantly laid upon the swollen palpebræ; and the powder (3) is to be given in gruel or syrup three times a day.

FEBRIS JUNIORUM REMITTENS.

I have used the word juniorum instead of infantum, as this remittent affects children from one year old to about ten. The cure of this disease is greatly promoted by medicine, if not wholly effected by it. The following is a sketch of the symptoms:—The bowels are irregular and generally inactive; there is a total loss of appetite, and a remarkably foul and undigested state of the fecal evacuations; the urine is high coloured; the pulse is rapid; there is a burning heat of the skin at night, with restlessness or delirium, but during the day there are several remissions, in which the child appears to be comparatively better, and drowsy. The cheeks are often flushed; the hands tremble; the nose and lips are constantly picked, and the child becomes peevish, and cries if an attempt be made to prevent it.

It is sometimes scarcely possible not to confound this

disease with the *early* stages of some inflammatory conditions of the brain.

There may be chilliness, vomiting, fever, with a rapid pulse, constipation, occasional drowsiness, restlessness and delirium in both. But if it be truly stated that this kind of remittent be derived from intestinal causes, then, by attentively observing whether, upon the whole, the symptoms point to the cerebral or abdominal functions, we shall be enabled to come to a sufficiently correct conclusion to direct the treatment. Acute headache, whether gestured or expressed, intolerance of light, starting in the sleep, and grinding of the teeth, would decide for the former; whilst the absence of these, irregular remissions of fever during the day, a burning skin in the night, and a disgust of food, would evidence the latter, and, therefore, the present disease.

The indications of cure are:—1st, to clear out the alimentary canal, and reduce the fever; 2nd, to improve the digestive function, and strengthen the system. The first will best be accomplished by Nos. 1, 2, and 3, and the second by 4.

CYNANCHE TRACHEALIS: INCIPIENT STAGE.

This disease is the result of inflammation of the mucous membrane of the trachea, and the deposit of false membrane upon its surface. The respiratory appears to be the only mucous membrane that is so frequently subject to fibrinous deposits; the conjunctival, the nasal, the cesophageal, and the urethral being almost exempt from such a result. It is difficult to explain why children should be so much more liable to croup than adults; it may be, that, as in the former the forces of physical growth are greater, so any inflammatory action of those

* Continued from page 698 of last volume.

forces are the more disposed to secrete fibrin. Whatever may be the true explanation, it is an established fact, that croup is seldom met with after the age of puberty. On the other hand, the younger the child the greater the danger, for then the respiratory tube is comparatively small, and liable to be more rapidly impeded by false membrane.

This terrible disease usually invades the trachea at night. The child, probably after some slight indication of cold, is awakened from sleep by an impediment to the breathing, and every effort to inspire produces a crowing sound; after this the breathing becomes more and more stridulous and straitened, and is accompanied with a shrill hoarse cough. There is sthenic pyrexia, and an anxious and distressed aspect.

It is scarcely possible to confound idiopathic croup with any other disease. In the spasmodic form there is no hoarse cough nor *continuously* stridulous breathing; neither is there much febrile disturbance or distress.

In laryngismus stridulus there is also a crowing sound, but this is transient, returns at intervals, and is attended with a sense of suffocation, which greatly alarms the little sufferer, and makes him instinctively dread a recurrence of the attack, for in one of these he not unfrequently expires.

A few years ago I was called to an interesting case of this kind in a remarkably fine boy, six months old. The spasms returned after intervals of several hours, and every recurrence threatened his existence, and dreadfully alarmed him, till at length, in spite of every remedy, the atmosphere was refused admittance through the glottis, and he suddenly expired.

Laryngismus does not appear to be the result of inflammation, but rather of a spastic reflex action of the arytenoid muscles, which act in closing the rima glottidis, and this action is often caused by teething.

The incipient stage of croup is amenable to treatment, if it be early and decided; but if the inflammation be allowed to creep on till false membrane is secreted upon the internal surface of the respiratory tube, all remedies will be ineffectual in nine cases out of ten. Local bleeding, calomel, and antimony, are the remedies mostly to be relied upon. Leeches are to be applied over the trachea, the number to correspond with the age of the child; and the powder (1) is to be given every two hours, till the stools assume a spinach colour, and the breathing is relieved.

Antim. Pot. Tart., gr. iss.
Sacchar. Purific., dr. ss.

Misce et divide in chartulas sex, quarum detur una secundâ quâque horâ.

This dose supposes the child to be over a year old. After the orifices of the leech-bites have ceased to bleed, a narrow blister may be laid along the sternum, and the warm bath may be necessary, if the skin be hot and dry. The diet should be low, such as barley-water, sweetened with honey, and the atmosphere of the room be of a genial temperature.

Croup is most commonly met with in damp and cold districts; and if the patient recovers he is sometimes

liable to a return of the disease: in such case he should be removed to a mild locality.

PETECHIAL SPOTS IN CHILDREN.

Petechiæ are most frequently observed in febrile diseases of an asthenic character, and in such they are to be looked upon as a very unfavourable symptom. I remember one instance of continued fever, in which the skin of the whole body was literally spotted with large petechiæ, and which soon terminated fatally. But petechiæ may also exist independently of any febrile association, and with this kind the purpura hæmorrhagica may be classed, although the spots are so much larger.

The case to which I allude in this place is unassociated with fever, and occurs to children from about six to twelve years old. Here also the petechiæ appear to be the result of a low power of the blood. They are generally seen on the inferior extremities between the knees and ankles, and are, for the most part, the size and appearance of flea-bites; sometimes, however, they are here and there interspersed with others of larger size, but all are of a deep purple colour. There is often, at the same time, pain at the epigastrium, aching of the joints, a foul and flabby tongue, a weak pulse, and a feeling of debility.

The indication of cure is simply to strengthen the system; and this will be fulfilled, and the petechiæ speedily removed, by the hydrochloric acid (1), the alterative (2), and a generous diet.

INTESTINODYNIA IN YOUNG PERSONS.

The assemblage of symptoms, to which I have ventured to give the above denomination, appears to be of a functional character, occurs before the age of puberty, and continues for a considerable time. It consists of a constant, dull, aching pain of the bowels, seldom accompanied with griping. The abdomen is enlarged, dull under percussion, and rather tender under deep pressure. There is no fluctuation to be discovered in the peritoneal cavity; neither is there any attenuation of the body. The pulse is quiet and regular; the tongue is not furred; there is no diarrhœa nor constipation; and the appetite varies, being sometimes excessive and sometimes altogether absent.

It is difficult to point out, with any degree of accuracy, the cause from which these symptoms are derived. They do not appear to be connected with the presence of entozoa in the alimentary canal, nor with glandular disease of the mesentery. I have rather attributed them to a congested state of the portal veins, but I am not at all certain of the correctness of this opinion. Not having met with any fatal termination of the disease, I have had no opportunity of ascertaining any facts that could better explain its pathology.

I have, in my experience, met with a considerable number of these cases, and they have yielded, in a remarkable manner, to the bichloride of mercury, after being taken a very few days. It may be given as in—

- 1.—R. Hydrarg. Bichlor., gr. iss.
Tinct. Card. Comp., Syrup. Zingib., sing. oz. ss.
Tinct. Hyosc., dr. j.
Aque Mentha Pip., oz. v.
M. Capiat cochleare largum unum ter quotidie.

In this dose the bichloride will generally give about two stools in the day. If it should operate too much, the dose must be reduced to 1-12th of a grain; if it fail to affect the bowels at all, some aperient will be required to regulate the bowels, such as ten grains of rhubarb, or one of the pills (2) every other night.

- 2.—R. Pilula Colocynth Comp. (L. P.), scr. ij.

Extr. Hyos., gr. vj.
Olei Caryophilli Guttam.

Misce et divide in pilulas xij.; capiat unam duasve alternâ quâque nocte, vel pro re natâ.

The two following cases are examples of this disease:—

Case 1.—C. B., aged 12, complained of a dull pain in the lower part of the abdomen, which had existed for some time; it was enlarged, and somewhat tender under pressure. The pain became worse about the middle of the day after his dinner. The bowels were neither constipated nor relaxed. The tongue was but little furred; the pulse did not exceed 90 in the minute, and the appetite not wholly absent. An eighth part of a grain of the bichloride of mercury, dissolved in peppermint water, was prescribed for the child three times a day, which at once relieved the pain, and in a short time reduced the size of the abdomen and removed the disease.

Case 2.—W. P., aged 11, had complained of an aching and pinching pain of the bowels for two months, it was occasionally so severe as to make him roll upon the floor. The abdomen was in some degree swollen and tender under deep pressure. He had one stool daily. He was thirsty, and his appetite was sometimes voracious, and at others altogether absent. The tongue, however, was not much furred, and there was no febrile disturbance. The same treatment was adopted in this case, and in a week afterwards the child was convalescent.

ENLARGEMENT OF THE ABDOMEN FROM MESENTERIC OBSTRUCTION IN YOUNG PERSONS.

The obstruction of the mesentery, here alluded to, is not that which is caused by strumous enlargement of its glands, nor that which results from the agglutination of its peritoneal surfaces by organised fibrinous deposits, both of which I consider to be incurable, but that which is occasioned by sub-acute inflammation, unattended with any great degree of febrile action.

This disease is characterised by enlargement, severe pain and tenderness of the abdomen, which is dull under percussion, and sometimes infiltrated. If the symptoms have continued for any length of time, there is also extreme atrophy.

The cases which have fallen under my observation have occurred from the age of ten to fourteen years.

In the treatment of this disease, calomel, combined with opium, has been, in my own experience, successful beyond all expectation, not only in subduing the severity of the pain, but in curing the malady; indeed such a result, in several instances, both from the severity of the symptoms and the atrophied condition of the patient, has greatly surprised me.

The pills (1) should be given two or three times a day, according to the degree of pain; and should ptyalism be produced, and the pain, nevertheless, continue, the opium is to be persisted in without the mercury, in such doses, and after such intervals, as the circumstances shall require.

- 1.—R. Hydrarg. Chlor., gr. vj.
Pulv. Opii, gr. iij.
Conf. Rosæ, scr. ss.

Misce et divide in pil. vj.; quaram capiat unam bis terve die urgenti dolore.

I have found a plaster also an excellent adjuvant, and very conducive to the removal of the disease. It should be made of equal parts of the Empl. Ammon. cum Hydr., and the Empl. Thuris Comp, spread upon thin leather, and large enough to cover the *whole abdomen*. This remedy appears to act not so much by virtue of any medicinal property in the plaster as upon the principle of gentle pressure, by which it gradually softens and reduces the abdominal enlargement, whilst the calomel and opium relieve the pain and subdue the inflammatory condition of the mesentery and of such other viscera as may be involved. The following is a most remarkable case of the kind, and will give the symptoms more in detail:—

A young female, aged 15, and before her menstruation had begun, became gradually affected with fulness of the abdomen, accompanied with darting pains of the lower part of the bowels, extending to the back. The pain was generally severe but worse in the night. There was not much febrile action, although she was often thirsty. At the commencement of the disease there was sickness and vomiting but not afterwards. Her food gave her gastric pain; her urine was high coloured; and her bowels were irritable, acting always after every meal. There was also a frequent desire to pass the urine. This state of things continued five months, the greater part of which time she kept her bed. She was then brought into Southampton and placed under my care in the dispensary.

The abdomen was now in some degree infiltrated, and so tender as not to bear the weight of the bedclothes. She was atrophied to the last degree, and could not stand without assistance. At the same time her appetite was ravenous and nothing could satisfy it. The pain of the belly was agonizing and it was distressing to witness her extreme suffering. With a view to mitigate the severity of the pain and without the least expectation of curing the disease, a large opiate plaster was applied over the whole of the abdomen, and calomel combined with opium, was given every four hours:—one grain of the former and as much of the latter as the vehemence of the pain required. This treatment was

continued for some time with manifest benefit, and under its continuance the pain, tenderness, and enlargement of the abdomen gradually subsided; in short, to my astonishment she completely recovered. She is now 27 years of age, and in good health.

CHOREA.

Chorea occurs from the age of about eight to fourteen years. Before or after this period it is seldom to be met with. It consists of an assemblage of sudden involuntary muscular actions, which are throughout the day continually distorting the features, and drawing the head, trunk, and limbs, into various abnormal attitudes.

This strange malady seems to be the result of an atonicity and a morbid sensibility of the excito-motory nerves. It is difficult to state, with any degree of precision, from what source these irregular movements take their origin; but it is probable that they commence in the ganglionic or sympathetic nerve, and are thence reflected through the spinal chord, upon the muscular system. This is a mere opinion, and must be taken as such: or it might originate in some part of the cerebral function; and this view is in some degree supported by the fact that the involuntary actions entirely subside during sleep.

Chorea is generally curable by medicine in six weeks or two months; and the remedies which I have found most successful, are preparations of iron and smart purgatives, as—

Pulv. Cinnam. Comp., gr. ij.
Misce capiat æger hanc dosin ter die in theriacâ.
- 2.—R. Hydrargyri Chlor., gr. iij.
Scammonii Gummi, gr. iv.
Pulv. Zingiberis, gr. ij.
Misce fiat dosis quâqua tertia nocte sumenda.

In some cases the magnetic oxide of iron answers better than the sesqui-oxide, as in—

- 3.—R. Ferri-Oxidi Magnetici, scr. j.—dr. ss.
Pulveris Zingiberis, gr. ij.,
Misce fiat dosis in crasso vehiculo sumenda ter quotidie.

Should the above preparations of iron fail to remove the disease, the iodide of potassium will be often found successful, especially if the strength has been much worn by the long continuance of the choreal movements. It may be given in the formula—

- 4.—R. Potass. Iodidi, gr. xxiv.
Syrupi Aurantii, oz. ss.
Aque Menthe Pip., oz. iiss.
Misce capiat æger, cochleare largum unum ter die ex aquæ pauxillo.

I saw this medicine succeed in a remarkable manner after all other remedies had failed, in a young man, 21 years of age, and six feet in height.* I have known chorea affect several members of the same family as they came to an age susceptible of the disease, in some of whom it proved fatal in spite of every means employed to subdue it. There are forms of chorea in which the

spastic actions of the muscles are so violent and incessant as to make it absolutely necessary to combine opiates with the above treatment. The following is an example of the kind.

J. C., of Romsey, aged 16 years, was admitted under my care, into the Royal South Hants Infirmary, on the 28th of August, 1848, for chorea. The spastic actions were so universal, violent, and incessant, that neither personal clothing nor bed-clothes could be kept on her for a moment, nor could she lie upon the bed without the risk of being jerked off it. Under these circumstances it became necessary to lay her on a mattress upon the floor of a small ward, taking care to pad the walls that she may do no injury to herself, and directing the nurse to keep a blanket on her as best she could. She was then ordered the following medicines:—The opiate (5) to be given every night; the magnetic oxide of iron with Dover's powders (6) three times a day; and the purgative (7) alternate mornings.

- 5.—R. Liq. Opii Sedativ., m. x.
Mist. camphore oz. ss. Fiat haustus omni nocte bibend.
- 6.—R. Ferri Oxidi Magnetici, gr. xv.,
Pulv. Ipecac. Comp., gr. iiss.
Misce fiat pulvis ter die capiend in crasso vehiculo.
- 7.—R. Pulv. Scammonii Comp., gr. x.
Fiat dosis omni alteruo mane sumenda.

This treatment at once succeeded. The spastic movements were speedily controlled, in two days she returned to her bed, and on the 25th of September, (twenty-eight days from her admission,) she was discharged cured.

Southampton, January 2, 1852.

[To be continued.]

ON PROLAPSUS UTERI.

WITH A DESCRIPTION OF A NEW INSTRUMENT FOR ITS TREATMENT.

By JOHN JONES, ESQ., DERBY.

Read at the Quarterly Meeting of the Midland Branch, December 4, 1851.

AMONGST the various infirmities to which the female constitution is subject none is more entitled to the grave consideration of the profession than the abnormal positions of the uterus. The displacement of this organ, when connected with pregnancy or the puerperal state, as in retroversion or inversion, require manual assistance, and if not speedily relieved, become highly dangerous; but the most frequent of all displacements is the descent of the womb, which, although not immediately dangerous, is productive of great and continued suffering. It occurs in three different degrees, thus defined by Dr. Ashwell:—

1. *Relaxation* implies that the uterus has lost its central projecting position in the upper part of

* The case was published by me in the *Provincial Medical and Surgical Journal*, May 1st, 1844.

the vagina, and has descended sufficiently far to obtain a bearing on the perineum, without, however, any material shortening of this canal or any marked alteration in the uterine axis.

2. *Prolapsus* signifies that the uterus has sunk nearly or quite down to the os exterum. Under this state the vagina is considerably everted, and the womb losing the axis of the brim, which is downwards and backwards, assumes the axis of the outlet of the vagina, which is downwards and forwards.

3. *Procidentia* implies complete protrusion beyond the vulva. The uterus forms a tumour, often very large, hanging out between the thighs, and the vagina turned inside out, constitutes the external covering. In the sac thus formed, especially if of long standing and large, there is contained the bladder, rectum, and some portion of the small intestines; the mesentery being stretched, and the omentum occupying any vacant space.

The descent of the womb, even in the first or slightest degree, is attended with much pain and constitutional irritation, the cause of which may readily escape notice. These symptoms are soon followed by those induced by mechanical pressure, constituting prolapsus, difficult micturition, which is performed most easily when in the recumbent position; a feeling of sinking of the abdominal contents, accompanied with a painful bearing down when walking or standing, which are immediately relieved by lying down; and leucorrhœa. In actual procidentia, the tumour is sometimes of immense size and altogether irreducible. I have seen a permanently protruded uterus forming a tumour as large as a child's head. Another occurs to my recollection in which the uterus protruded beyond the vulva, and exposed to friction, became ulcerated to the extent of a crown piece, and of course was productive of long-continued and grievous suffering.

This infirmity is most frequent amongst the lower ranks of society, with whom it is induced by exposure to hard work and privation. Such patients, believing that their malady admits of no remedy, seldom complain, and thus they pass through a life of suffering, embittered by concealment, often without medical aid, and deprived even of the soothing sympathies of friendship. Persons, however, of all ranks, are more or less subject to this disease, especially those who have borne many children, and even virgins are not exempt.

Causes.—These are:—weakness and undue expansion of the broad and round ligaments, together with relaxation of the levator ani and perineal muscles; but particularly as observed by Dr. Ashwell, “and extension and slackness of the pelvic fascia in its connection with the uterus and vagina.” The principal cause, however, and which will account for most of its painful symptoms is, I conceive, the superincumbent weight of the abdominal viscera pressing on the uterus, deprived of its usual supports by the relaxation of the vagina and neighbouring parts. That such pressure is a powerful agent in producing the disease, is proved by the freedom from all uneasiness when the patient is in the recumbent position

and the immediate and great relief afforded by well-adapted means for supporting the abdominal parietes.

Treatment.—In prolapsus and procidentia, mechanical means for supporting the uterus have hitherto been alone depended upon by the profession generally, as affording the most approved mode of relief; and these supports have consisted almost exclusively of pessaries, modified in shape and the material of which they are composed, according to the ingenuity and fancies of different practitioners. The inconveniences, however, produced by pessaries, the untoward symptoms which they sometimes induce, and the inefficient relief they afford, render their use exceedingly unsatisfactory. Sir Charles Clarke, who is a strenuous advocate for the use of the pessary, relates the following case:—

“A lady, seventy-five years of age, who had borne children, came under the care of the author, on account of considerable pain in the vagina, attended by a very offensive discharge. The pain was constant, and was compared to that produced by a sharp instrument. Thirty-five years before she had a prolapsus uteri, for which a pessary had been introduced, and which had never been removed. The author having reason to fear that some diseased structure existed, examined the patient and found that the pessary had lost its original form, being corroded in several places, and that many irregular portions of it were left, which pressed upon the vagina, and had produced ulceration of its internal surface. This lady having, as she said, suffered exceedingly in the introduction of the instrument (because, perhaps, it was incautiously performed) would not consent to its removal, particularly after some of her symptoms had been relieved by fomentations and injections.”

The great inconveniences attending the use of pessaries have induced some practitioners to discard them altogether, and to substitute for them a painful if not dangerous operation, for the purpose of contracting the vagina, so as permanently to prevent the descent of the uterus, and thus effect a radical cure. Dr. Marshall Hall is amongst those who advocate this mode of treatment. It is, however, too formidable an operation to be generally adopted, and to which few patients would be willing to submit, more particularly as the results are not always satisfactory, and, at least, partial relief can be obtained by less severe means.

Some years ago Dr. Hall invented an instrument for the purpose of keeping *in situ* the procident uterus by external pressure, and thus to supersede the use of pessaries. Dr. Ashwell gives the following description of it:—“A pad, elastic but firm, is made to bear upon the perineum, without interfering either with the rectum or vulva. A belt round the waist, and a connecting strap, passing from before to behind, aided by springs and hooks, secures sufficiently firm compression to prevent the descent of the replaced womb. Several of my patients have worn this pad comfortably, and with tolerable success; but in most cases the pressure has induced pain, heat, and leucorrhœa; and they have gladly exchanged it for the pessary. The expense of these more elaborate instruments is to poor woman, in

whom the disease is most common, a serious matter, especially as they frequently want repair. On the whole, I regard the pessary as by far the most applicable, and generally the most efficient remedy for proclentia."

In the early part of my practice I met with a very painful case, in which a pessary had been worn for a long time, with considerable relief; but at length it produced pain and great discomfort, so that its removal became necessary. It was a common circular ring-pessary, and so firmly fixed that I was unable to move it by the utmost force I could use with my bent finger, and was obliged to pass a ligature through the ring, and pulling with great force, at length extracted it. Since that time, now upwards of twenty years, I have generally recommended the application of two pads attached to a belt, one to be applied to each side of the lower part of the abdomen, so as to press upwards, with the view of supporting the abdominal viscera. From the great relief afforded by this simple plan, I felt confident it was fulfilling an important indication; and from that time have availed myself of every opportunity of improving the belt, and rendering it more perfect in its adaptation and efficiency.

The belt, or uterine truss (which is its appropriate designation), supplies a most important desideratum, by entirely superseding the necessity for the use of the pessary—an instrument which has hitherto been considered by the profession generally indispensably necessary in the treatment of prolapsus uteri. By supporting the perineum, and at the same time preventing the pressure of the abdominal viscera, it fulfils two important indications,—that of strengthening those parts which by their relaxation have allowed the descent of the uterus, and removing the pressure on the uterus produced by the superincumbent weight of the abdominal viscera. In cases of pregnancy occurring during prolapsus, if the recumbent position is continued sufficiently long after labour, the disposition to descent of the womb is greatly diminished, and sometimes the disease completely removed. In these cases the relaxed parts are allowed time to recover their natural healthy tone before they are again exposed to the pressure of the descending uterus. The application of the belt greatly assists in retaining the uterus *in situ*, and preventing a return of the disease; and in all cases of descent of the womb it not only gives great and immediate relief, but, by removing the pressure of the uterus from the relaxed parts, it tends to effect a permanent cure.

The following interesting case recently occurred to me, in which the belt was found very useful:—A. D., about 30, is suckling her second child, eleven months old. In her first pregnancy she was affected about the fourth month with retroverted uterus, which I reduced, and she went to the full period of gestation. She believes she is not now pregnant; but the catamenia have not appeared since her confinement. For a week or two before I saw her she had been affected with symptoms of retroversion, and walking or standing produced great pain. On examination, I found the

fundus uteri pressing very low, about the size of a small melon, somewhat flaccid, and projecting between the rectum and vagina. The os uteri, which I could with difficulty distinguish, was situated on the symphysis pubis; the cervix was completely bent upon itself, like a bent finger. I returned the uterus without much difficulty, and passed it beyond the promontory of the sacrum, and afterwards applied the belt, since which she has been completely relieved from all her distressing symptoms.

I consider the above case an instance of *retroflexion* of the unimpregnated uterus, the possibility of which is denied by some practitioners, and others believe that it can only occur soon after labour. The application of the belt I consider of great importance in preventing the recurrence of such an accident.

DESCRIPTION OF THE UTERINE TRUSS.

It consists—1, of a belt with two pads, to support the abdominal parietes; 2, a bandage with one pad, to support the vulva and perineum.

The belt, four inches and a half broad, is made of strong holland, lined with wash leather, and padded with horse-hair. Two pads, united by a strip of vulcanized India-rubber, one inch and a half broad and three inches and a quarter long, are placed between the end of the belt and a leather strap, which buckles on one side. The belt is strengthened by five sticks of whalebone placed obliquely at equal distances of about four inches. The pads, three inches and a half in diameter, consist of two convex circular plates of tin, the inner rather smaller than the outer one, made to act upon each other by an interposed spiral spring. The whole is padded with horse-hair and covered with mackintosh. In the centre of the outer plate of each pad is a button for the attachment of the perineal bandage. A laced gusset is formed on each side of the belt, for its easy adaptation to the hips; and loops of tape are placed at the top, to attach it to a waistcoat, which, however, is seldom required.

The perineal bandage consists of an anterior and posterior flap, united by a strip of vulcanized Indian-rubber, one inch and a half long and half an inch broad. Within the anterior flap is a pad four inches long, stuffed with horse-hair, and covered with mackintosh, intended to support the vulva and perineum. Each flap, four inches broad at the top, has six button-holes, in two rows, one above the other, corresponding with buttons on the belt; these give considerable scope for the lengthening or shortening of the perineal bandage. The flaps are made gradually to become narrower, to be joined to the interposed strip of Indian-rubber.

The resiliency produced by the horse-hair stuffing, and the elasticity afforded by the Indian-rubber, render the belt easy to wear, and efficient in its application.

FRACTURE OF THE HUMERUS AT ITS LOWER-THIRD.

By ROBERT E. JONES, Esq., LONG MELFORD.

On the 6th of September, in consequence of the absence of Mr. Mason, of Sudbury, I was hastily summoned to visit Eliza Harrington, aged 15 months, the child of poor parents, residing at Wickham St. Paul's, Essex, who had been knocked down by a waggon, the wheel of which had passed over her left arm. On examination I found a fracture of the humerus at its lower-third, the bone protruding denuded of its integuments, and the soft parts lacerated nearly to the shoulder-joint. The little patient was much exhausted from loss of blood. I administered small quantities of brandy and water, which had the effect of producing reaction; and feeling there was no time to be lost, I at once amputated just below the shoulder-joint, being just able to save sufficient integument to form a good stump. I was ably assisted by Mr. Mason, jun. Very little blood was lost during the operation, and but one artery required a ligature. The child had severe convulsions the following day, which were relieved by small doses of tincture of opium, after which it progressed most favourably, and at the end of a month was perfectly recovered. I am induced to publish this case, thinking it rare for a child of such a tender age to recover from so severe a proceeding.

Long Melford, Suffolk,
November 20, 1831.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CASES ADMITTED UNDER DR. DAVID NELSON.

Reported under the terms proposed by the Association.

By OBSERVATOR.

Case of Inflammation of the Brain.

THE following case affords a striking illustration of the insidious manner in which so formidable and mortal a disease commences and progresses, fully showing the necessity of a careful and guarded diagnosis in all head affections. The preceding case of Barrett, in which the symptoms were similar, affords, as to the result of the cases, an instructive contrast, probably to be, in a great measure, accounted for by the fact, that Barrett had the advantages of being a young man, and of receiving timely medical aid, which two advantages experience proves to be of vast importance in the successful treatment of such cases.

Daniel Yates, aged 58, of nervo-sanguineous temperament, became an in-patient of the Queen's Hospital, Birmingham, under Dr. Nelson, on the 18th of January,

1851, having been an out-patient for a week previous to admission.

History.—He was a gardener in a private establishment, and one night, about two months prior to his admission as an in-patient, he was summoned to extinguish a burning hayrick; whilst thus engaged he said he felt as if "roasted to death, and very much excited." When he had worked an hour or two he became completely exhausted, and on reaching home felt pain in the head, with shivering and loss of appetite. Throughout that night he had fearful dreams, and on waking next morning experienced a deficiency of muscular power, which he and his friends attributed to mere exhaustion, and thought he would get right in time. Time proved that his mental and muscular powers were gradually failing, when his friends took him to the hospital for advice.

On entering the physician's room his head and knees bent forward, inclining a little to the right side. His gait was staggering and unequal, and he exhibited an indifference of manners, and *appeared* like a man half asleep, or stupified by intoxication. When desired to put out his tongue or move his lips, he obeyed, and continued the acts until told to cease them. His replies were intelligent and respectful, but his mind soon wandered from the point. His head was hot, and tongue furred. The application of cold to the head, the insertion of a seton in the nape, and the use of purgatives, were ordered; but he became worse, and being unable to walk to and from the hospital without support, he was desired to become an in-patient.

Symptoms.—On admission his mind was evidently impaired; there was great heat of scalp; the countenance flushed; the tongue was much coated; his appetite was bad; bowels obstinate; and the left extremities were somewhat rigid.

Indications.—To abate inflammatory action, and restore tone, if possible.

Treatment.—The seton was ordered to remain, and he took colocynth pills at night, and a saline purgative in the morning, and pills of sulphate of zinc and extract of gentian thrice a day.

21st.—He was reported to have gone on well, but on the previous night had fallen out of bed, and the pain in the head had returned; he slept very little; his appetite was very keen. Continued the medicines, and applied six leeches behind the ear.

24th.—He was in bed, and drowsy, having had another fall, striking his head against the bed-post; seemed to be getting worse and worse. Continued the medicines.

31st.—His powers of intelligence and motion seemed to be rather improved, and he did not complain of pain, whilst the bowels were regular. Continue medicine.

February 4th.—It was reported that he had been tolerably well until that morning, when he had had another fall on his head, which compelled him to go to bed. He lay drowsily, with his feet drawn upwards, and his head inclined downwards. The bowels were very costive. Continued the medicines, with the addition of one drop of croton oil every morning.

11th.—His intellectual and muscular powers were again a little improved, and his bowels were open, but he was drowsy and weak. Instead of sulphate of zinc he took phosphate of iron, and continued the other medicines.

14th.—It was reported that he had been better, having walked about the ward, and taken his meals at table for three days past. Continued the croton oil and phosphate of iron.

18th.—He continued to go on favourably as before.

21st.—He was still walking about, and talking, not having had a fall for several days. Continued the medicines.

28th.—It was found that he had continued as above until the morning of that day, when he had bilious vomitings. He had four drops of hydrocyanic acid, and after that a dose of calomel.

March 4th.—His intellect was tolerably clear, and the bowels were regular, but he staggered in walking. He was now ordered blue pill and colocynth every night, and Epsom salts and magnesia in the morning, while he continued the phosphate of iron.

14th.—He was going on much the same, but on that day drowsiness came on, with torpidity of the bowels, though the urine was plentiful. This state proceeded on to coma, not preceded by any degree of convulsion or delirium. He lay quietly, with the left pupil at first dilated alone, with easy respiration, and a full steady pulse of 60. There was a slight general rigidity of the body, both pupils became dilated and were directed upwards, and he died, but without any stertorous breathing.

Post-mortem appearances.—On opening the head the skull-cap and dura mater were found to adhere more strongly than usual, but was otherwise healthy. There was congestion of the sinuses and all the superficial veins. The left hemisphere was perfectly healthy, but a very extensive portion of the posterior part of the right hemisphere was completely softened into a pulsataceous mass, very much resembling thick cream, coloured with strawberry. This mass had fluctuated so as to form a kind of pouch, which pushed the lateral ventricle toward the left side, but had not opened into it. The softened part was about four inches and a half by two inches and a half, and no other lesion of importance could be found.

The anomalous and uncertain symptoms which so often attend such lesions are in this case well illustrated. The alternations of stupor and watchfulness were very remarkable, and indeed the whole history is highly characteristic of the insidious rise and progress of the disease.

Case of Syphilitic Rheumatism.

SIMPLE rheumatism is generally a tractable disease, and soon yields to treatment when occurring in a healthy subject, but when it affects a constitution already debilitated and vitiated, it is frequently very obstinate and troublesome, as the following case will prove:—

John Bradnock, aged 28, of nervo-lymphatic temperament, was admitted an in-patient of the Queen's Hospital, Birmingham, under Dr. Nelson, on the 21st of October, 1850. He stated that he had formerly suffered severely from syphilis. About four months prior to admission he took cold, (of which he was very susceptible,) which was followed by an attack of rheumatism, at first in the right ankle, and then in other parts of the body.

Symptoms.—He was tall, pale, thin, and haggard, the countenance indicating a syphilitic taint; the tongue was covered with a white fur; the urine clear, and no pain in his back; the ankles were rather swollen, and all the joints painful; sounds of the heart natural; pulse 130, very weak.

Diagnosis.—Rheumatism, arising from syphilitic debility.

Indications.—To produce healthy secretions, and improve the general health.

Treatment.—He took colchicum, hyoscyamus, and tartrate of antimony, with an alkaline draught, thrice a day, and was ordered a warm bath at bed-time.

22nd.—There was no change; the bowels were costive, and sleep disturbed. Continued the medicines, and was ordered calomel and hyoscyamus every night.

25th.—He was easier, but the right hand and knee were much swollen. Continued the medicines. The swollen parts to be punctured with a lancet, and placed in warm water.

28th.—The pain had diminished, and the swellings subsided. Continued the medicines.

November 5th.—The pains had become more severe; tongue still furred. Aconite was added to the mixture. The other medicines to be continued.

8th.—The pains were again easier, and they remained so to the 15th, when he could move his joints tolerably well; pulse 96. He continued the mixture thrice a day, and took a Plummer's pill every night.

19th.—He had only slight pains in the shoulders; the urine deposited a red sediment; and he had several dark blotches on his body; his aspect continued pale and ghastly. To continue the medicines, and take two drachms of cod-liver oil night and morning.

He continued to improve slowly, with occasional returns of deep-seated gnawing pain, and on the 29th ceased taking the colchicum, but continued the Plummer's pill every night, and took a draught, consisting of iodide of potassium, conium, sassafras, and scopolium, thrice a day.

December 13th.—The blotches had become paler, and on the 27th he was convalescent, and left the hospital pale and thin, but free from pain, blotches, &c.

In this case there were persistent gnawing pains for about three months, which gradually diminished, but were not eradicated till near the end of the treatment. Their gradual yielding was no doubt due to the continued use of colchicum and diaphoretics.

Provincial Medical & Surgical Journal.

WEDNESDAY, JANUARY, 21, 1852.

WE have great pleasure in publishing a draft of a bill entitled "A Bill to produce Uniformity of Medical Education and Qualification, and for the Registration of those Licensed to Practise in Medicine," which has been for some time in course of preparation by a small number of the members of this Association; these gentlemen, however, would of themselves have been unable to complete their task, but that it fortunately happened that the talented son of our Founder is by profession a barrister, and has been induced to lend his powerful aid in drawing the technicalities so essential to the success of the measure.

It will be unnecessary for us to explain the Bill, since it is so clear in its details that "he who runs might read." But we may remark, that it has been drawn up with a desire to comply with the previously expressed views of this Association, and also with the intention of avoiding, as much as possible, doing injustice to any existing Corporation, or individual, privileges. The grand principles of the Bill may be enumerated as follows, viz., uniformity of primary qualification, which should be sufficiently high to ensure protection to the public; reciprocity of practice; protection against quackery and irregular practice, by means of registration; and last, though not least, the establishment, by the same machinery as is required for these purposes, of a fund which shall ensure all medical practitioners who register themselves, against illness, or in case of death, their wives and families, and this not as a matter of benevolence but as a right.

Of course it must be obvious that this Bill can only come into operation after the granting of the proposed New Charters to the College of Physicians and Surgeons; but as these Charters only wait the sanction of the profession, they may be considered *in esse* for all practical purposes.

Our space will not allow us to go more into particulars, nor perhaps is it desirable at present to do so; we should be anxious to obtain and publish the opinion of our members on the subject, since the Bill must stand or fall, (as far as its present supporters are concerned,) by the fiat of the Association, expressed through the

Branches, or by individual members through the *Journal*.

The Worcester Council has desired us to publish the annexed resolutions, which are as follows:—

"At a meeting of the Council of the Provincial Medical and Surgical Association, held on the 17th day of June, 1851, a draft of a proposed Bill, entitled 'A Bill to produce Uniformity of Medical Education and Qualification, and for the Registration of those Licensed to Practise in Medicine,' was submitted for approval by a Committee composed of members of the Association, who have long given the subject their careful consideration. It was resolved, that the Bill, so prepared, seems to carry out the principles of Medical Reform so long advocated by the Association, and that it is, therefore, highly desirable that the same should be forwarded by the Secretary to the Branch Associations; and that they should be requested to report to him their opinions on the various clauses composing the Bill, with as little delay as possible."

"The Worcester Council consider that the Bill can only be satisfactory to the profession if accompanied by new Charters to the Royal Colleges of Physicians and Surgeons, and although they do not think themselves called upon to express any opinion on the proposed Bill, they cannot avoid impressing upon the members generally the importance of the measure, and the necessity of unanimity, if any progress is to be made in the ensuing Session of Parliament."

DRAFT BILL.

"TO PRODUCE UNIFORMITY OF MEDICAL EDUCATION AND QUALIFICATION, AND FOR THE REGISTRATION OF THOSE LICENSED TO PRACTISE IN MEDICINE."

PREAMBLE.—Whereas it is for the good of all Her Majesty's subjects that the knowledge of physic and surgery should be promoted, and that means should be afforded whereby those who have been examined and found skilful by competent authority may be known from ignorant and unskilful pretenders to the same knowledge: And, whereas the laws now in force concerning the profession of physic and surgery require to be amended: Be it enacted, by the Queen's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same:

I. *Repeal of Statutes*.—[3 Hen. 8, c. 11.]—That an Act passed in the third year of the reign of King Henry

the Eighth, intituled, "An Act for the appointing Physicians and Surgeons;" and also

5 *Hen. 8, c. 6.*] another Act passed in the fifth year of the same reign, intituled "An Act concerning Surgeons to be discharged of Quests and other Things;" and also another Act passed in the Session of Parliament

14 & 15, *Hen. 8, c. 5.*] holden in the fourteenth and fifteenth years of the same reign, intituled "The Privileges and Authority of Physicians in London;" and also

32 *Hen. 8, c. 40*] two Acts passed in the thirty-second year of the same reign,

33 *Hen. 8, c. 42.*] respectively intituled, "For Physicians and their Privilege," and

"For Barbers and Surgeons; and also another Act passed in the Session of Par-

33 & 34, *Hen. 8, c. 8.*] liament holden in the thirty-third and thirty-fourth years of the same reign, intituled, "A Bill that Persons, being no common Surgeons, may minister Medicines, notwithstanding the Statute;"

1 *Mary, Sess. 2, c. 9.*] and another Act passed in the first year of the reign of Queen Mary, intituled, "An Act touching the Corporation of Physicians in London;" and also an Act passed in the Session of

6 & 7 *Wm. 3, c. 4.*] Parliament holden in the sixth and seventh years of the reign of King William the Third, intituled "An Act for exempting Apothecaries from serving the offices of Constable, Scavenger, and other Parish and Ward Offices, and from serving on Juries;" and so much of every other Act as continues the last recited Act; and also an Act passed in the tenth

10 *Geo. 1, c. 20.*] year of the reign of King George the First, intituled, "An Act for the better viewing, searching, and examining of all Drugs, Medicines, Waters, Oils, Compositions, used or to be used for Medicines, in all places where the same shall be exposed for Sale, or kept for that purpose, within the City of London or Suburbs thereof, or within seven miles circuit of the said City;" and so much of another Act passed in the

18 *Geo. 2, c. 15.*] eighteenth year of the reign of King George the Second, intituled,

"An Act for making the Surgeons of London and the Barbers of London two separate and distinct Corporations," as does not relate to the separation of the said corporations, or to the master, governors, and commonality of the mystery of barbers of London; and also so much of an Act passed in

55 *Geo. 3, c. 194.*] fifty-fifth year of the reign of King George the Third, intituled, "An Act for better regulating the Practice of Apothecaries throughout England and Wales," as relates to the examination of apothecaries, or to the qualifications of persons intending to be examined or to qualify themselves under that Act to practice as an apothecary, or to the fees to be paid by apothecaries for the certificate of the Court of Examiners, or to the penalties for

practising as an apothecary without having obtained such a certificate; and also

6 *Geo. 4, c. 50, s. 2.*] so much of an Act passed in the sixth year of the reign of King George the Fourth as enacts, that all members and licentiates of the Royal College of Physicians in London actually practising; all surgeons being members of the Royal Colleges of Surgeons in London, Edinburgh, or Dublin, and actually practising; all apothecaries certified by the Court of Examiners of the Apothecaries' Company, and actually practising, shall be freed and exempt from being returned, and from serving upon any juries or inquests whatsoever, and shall not be inserted in the lists to be prepared by virtue of that Act; and also so much of any Act or Charter granted before the passing of this Act as prohibits any person from practising physic or surgery in any place without such license as is mentioned in such Act or Charter respectively, or as imposes any restrictions on the practice of physic or surgery other than is contained in this Act, shall be repealed and annulled.

II. *Interpretation Clause.*—[To be inserted when the Bill is completed.]

III. *Appointment of the Medical Council for England.*—That a Council shall be established, which shall be styled—"The Medical Council for England;" and that the Regius Professor of Medicine in the University of Oxford, the Regius Professor of Physic in the University of Cambridge, and such one of the Medical Professors in the University of London as shall be from time to time designated by the Senate of the last-named University, shall be Members of the said Council in right of their several Professorships; and that the other members of the said Council shall be six persons, to be chosen by the Royal College of Physicians of England, (not more than three of such six persons being fellows of the said College,) six persons to be chosen by the Royal College of Surgeons of England, (not more than three of such six persons being fellows of the College,) and six persons to be chosen by the Society of the Art and Mystery of Apothecaries of the City of London, (not more than three of such six persons being members of the governing body of the Society;) each of the said appointments to be made within one month after the passing of this Act; and the powers and duties vested in the said Council by this Act, may be exercised and executed by any six members thereof.

IV. *Tenure of Office by Members chosen by the Colleges.*—That every member of the said Council appointed by the said College of Physicians, the said College of Surgeons, and the said Society of the Art and Mystery of Apothecaries, shall be entitled to be a member of the said Council for three years, and shall then go out of office, but may forthwith be re-chosen; and that upon every vacancy among the members of the said Council, appointed by the said College of Physicians, the said College of Surgeons, and the said Society of the Art and Mystery of Apothecaries, and

their successors, the said College of Physicians, or the said College of Surgeons, or the said Society of the Art and Mystery of Apothecaries, as the case may be, shall appoint another person to supply such vacancy.

V. *Appointment of the Medical Council for Scotland.*—[To be inserted hereafter.]

VI. *Tenure of Office by Members of the Medical Council of Scotland.*—[To be inserted hereafter.]

VII. *Appointment of the Medical Council for Ireland.*—[To be inserted hereafter.]

VIII. *Tenure of Office by Members of the Medical Council for Ireland.*—[To be inserted hereafter.]

IX. *Expenses of the Members to be paid.*—That there shall be paid to the members of the said several Councils, such reasonable expenses incurred by the said members in performance of their duties under this Act, not exceeding three guineas for each attendance, as shall from time to time be allowed by the said several Councils.

X. *Each of the said Councils to Elect a President and Vice-President.*—That the said Councils shall, as soon as may be after they shall have been appointed as hereinbefore provided, meet at the following places: that is to say, the Council for England at the building of the Royal College of Physicians in London, the Council for Scotland at the building of the Royal College of Physicians at Edinburgh, and the Council for Ireland at the building of the King's and Queen's College of Physicians in Ireland, and shall each of them elect one of their members to be their president, and another of their members to be their vice-president; and in all cases every question brought before any of the said Councils shall be decided by a majority of votes, (the president, or, in his absence, the vice-president, having a vote), and in the event of an equality of votes, the president, or, in his absence, the vice-president, shall have an additional or casting vote.

XI. *Each of the Councils to appoint an Examining Board.*—That each of the said Medical Councils shall, within a month after their first meeting, appoint such fit and proper persons as the said Councils may severally choose, to form an Examining Board for the purpose of carrying into effect the provisions of this Act; and every member of such Examining Board shall be paid such yearly salary as the Council by whom he shall have been appointed shall think fit, and shall hold office for such period as the said Council shall determine.

XII. *Provisions as to the appointment of a Treasurer, Registrar, and Secretary, and of Clerks and Servants, and for the making of a Seal by each of the said Councils.*—That each of the said Councils shall, within a month after their first meeting, appoint a fit and proper person to be their treasurer, and also another fit and proper person to be their registrar and secretary; and there shall be paid to each of such treasurers and registrars such yearly salary as the Council by whom he shall be appointed shall think fit; and each of the said

treasurers and registrars shall be removable at the pleasure of the Council by whom he shall have been appointed; and each of the said Councils shall also, from time to time, appoint such clerks and servants as they may deem necessary for the purposes of this Act; and every person so appointed shall be removable at the pleasure of the Council by whom he shall have been appointed, and shall be paid such salary as the Council by whom he shall have been appointed shall think fit; and each of the said Councils shall cause to be made a seal for their use in the execution of this Act, and shall cause to be sealed or stamped therewith all licences granted or issued by them in pursuance of this Act, and all such licences and other documents purporting to be sealed or stamped with any such seal shall be received as *prima facie* evidence in all courts and places whatsoever.

XIII. *As to Registration of Medical Practitioners in practice before the passing of this Act.*—That the registrar of each of the said boards shall, within thirty days after his appointment, and shall from time to time, till the first day of February, one thousand eight hundred and fifty-three, proceed to register, in books to be kept for that purpose, on payment of a fee of five shillings, the name and place of abode, together with a description of the testimonials of every physician, surgeon, and apothecary who shall apply to be registered, and who, prior to the first day of November, one thousand eight hundred and fifty-two, shall have taken a degree in medicine in any English, Irish, or Scotch University, or who shall state his place of abode and apply to be registered, and shall produce his diploma, certificate, or licence, or shall produce a duly attested certificate, or such other proof as shall be satisfactory to the said registrars, of his having obtained a diploma, certificate, or licence to practise as a physician, surgeon, or apothecary, dated prior to the said first day of November, one thousand eight hundred and fifty-two, and granted by any English, Irish, or Scotch College or Hall, or any corporation sole or aggregate in England, Ireland, or Scotland, legally entitled to grant the same at the time of the passing of this Act, and also to every person who shall apply for the same, and who was actually practising medicine in England and Wales prior to the first day of August, one thousand eight hundred and fifteen, and who shall sign a declaration according to the form in schedule (A) to this Act annexed, and also to every surgeon and assistant-surgeon of the Army and Navy who shall apply for the same, and whose warrant of appointment bears date prior to the said first day of August, one thousand eight hundred and fifteen, and to every person who shall have been registered as aforesaid the said registrars shall give a certificate according to the form in schedule (C) to this Act annexed, and which certificate shall be in force till the first day of February, one thousand eight hundred and fifty-three, and no longer.

XIV. *Every Person not Registered as aforesaid to present himself before the Council of his country for Examination. Licences to be granted to those duly qualified on payment of a Fee of £10.*—That each of

the said Councils shall meet at least once in every four weeks, for the dispatch of business; and every person not being registered under the provisions of the next preceding section of this Act, who intends to practise medicine after the first day of February, one thousand eight hundred and fifty-three, shall present himself before the Medical Council for the country in which he intends to practise, and if such Council shall consider the person so presenting himself to be properly qualified as hereinafter is mentioned, they shall direct their Registrar to grant to such person a licence according to the form in schedule (B), to this Act annexed, on payment of a fee of ten pounds; and shall also register, in books to be kept for that purpose, the name and place of abode of such person, and shall also give to such person a certificate according to the form in schedule (C), to this Act annexed; and which certificate shall be in force until the first day of February then next ensuing, and no longer; and every person to whom such licence shall have been granted as aforesaid, shall be entitled to assume the name and title of a licentiate in medicine, surgery, and midwifery.

XV. *Candidates for Licences to produce Testimonials to the Medical Council.*—That every person who may present himself before any of the said Medical Councils for the purpose of obtaining a licence to practise medicine, shall produce proofs to the said Council that he has attained the age of twenty-one years, and shall also produce such testimonials as shall be satisfactory to the said Council, that he has applied himself to the study of medical and surgical science during a period of four years, and that during the aforesaid period he has passed at least three years in some University or Medical School, approved of by the said Council; and that he has attended such courses of dissection, such clinical and other lectures, and such hospital practice, and has passed such several examinations before the Examining Board appointed by the said Council, as the said Council shall from time to time appoint.

XVI. *Triennial Medical Congress to be held.*—That once in every three years each of the said Medical Councils shall depute three of their members to form a Medical Congress, for the purpose of fixing an uniform curriculum of study, in accordance with the next preceding section of this Act, to be gone through by all candidates for licences to be granted by the said Councils respectively; and such Medical Congress shall meet in London at such place and time as the Medical Council for England shall determine; the first Medical Congress to be held as soon as may be after the election of the said several Medical Councils.

XVII. *Registrars to Issue Annual Certificates to Registered Practitioners, on payment of a fee of 20s.*—That the registrars of each of the said Councils shall from time to time issue a certificate, according to the form in schedule (C), to this Act annexed, to every person who shall be registered as aforesaid, and who shall apply for such certificate; and the said Registrars shall issue such certificates for the countries only for which they shall be severally appointed to act: and every person shall, upon his application for such certificate, pay to the

registrar a fee of twenty shillings; and such certificate shall bear date on the first day of February then next ensuing, and shall continue in force during one year, and no longer.

XVIII. *All Monies received by the Registrars to be applied for the purposes of the Act.*—That all monies received by the Registrars of the said several Councils shall be paid over to the Treasurers of the said several Councils; and shall be applied to defray the expenses of carrying this Act into execution, in such manner as the said Council shall direct; provided always that one half of the monies received on account of the certificates hereinbefore mentioned shall be applied to the formation of a Medical Provident Fund for England, Scotland, and Ireland respectively, under the direction of the said several Councils; and every person who shall have been registered under this Act, and shall have obtained a certificate during ten years, or, in case of his death, his widow or children, shall be entitled to claim relief from the Council of that part of the United Kingdom in which he shall have been registered, out of the monies of their Medical Provident Fund.

XIX. *Application of Surplus Income.*—That if, after paying the expenses of carrying this Act into execution, any surplus income, other than the monies hereinbefore directed to be applied to the formation of a Medical Provident Fund, shall remain in the hands of the Treasurer of any of the said Medical Councils, such surplus shall be applied for the founding or establishing of medical scholarships or prizes, or in promoting the advance of medical science and literature, in such manner as such Medical Council shall determine.

XX. *Each Registrar to keep a record of Certificates.*—That the registrar of each of the said Councils shall duly record an account of every certificate which he shall issue as aforesaid; and in the month of February in every year shall cause to be printed a correct register, according to the form in schedule (D,) to this Act annexed, of the names and places of residence, arranged alphabetically, of all persons to whom he shall have so issued certificates during the year then last past, according to the provisions of this Act, together with a description of the legal qualification or qualifications, with the date or dates thereof, of all persons registered under the thirteenth section of this Act, and specifying the date of the licence granted by the Council, and the degrees and diplomas with the date or dates thereof, possessed by all persons registered under the fourteenth section of this Act; and such registers shall be respectively called, "The Medical Register for England," "The Medical Register for Scotland," and "The Medical Register for Ireland;" and a printed copy of the register for the time being, so published as aforesaid, shall be evidence in all courts, and before all Justices of the Peace and others, that the persons therein specified have obtained certificates according to the provisions of this Act; and the absence of the name of any person from such printed copy shall be evidence, until the contrary be made to appear, that such person has not obtained a certificate according to this Act.

XXI. Registered Persons Entitled to Practise where Certificates are Issued; and to Transfer their Names to the Register of other parts of the United Kingdom.—

That every person who shall be registered, and shall possess a certificate in force, according to the provisions of this Act, shall be entitled to practise medicine throughout that part of the United Kingdom for which his certificate was issued; and every person who shall be registered in one part of the United Kingdom may transfer his name to the register of any other part of the United Kingdom in which he may be about to practise, on production to the registrar of the last-named part of the United Kingdom of his licence and certificate for the current year; and the registrar shall thereupon grant to such person so transferring his name a certificate which shall remain in force till the first day of February then next ensuing.

XXII. No person to assume the Name of Physician or Surgeon who is not duly qualified.—That no person shall be entitled to assume the name or style of a Physician who is not, in England, a member of the Royal College of Physicians of England, or in Scotland, a member of the Royal College of Physicians of Edinburgh, or in Ireland, a member of the King's and Queen's College of Physicians in Ireland; and no person shall be entitled to assume the name or style of a Surgeon who is not, in England, a member of the Royal College of Surgeons of England, or in Scotland, a member of the Royal College of Surgeons of Edinburgh, or in Ireland, a member of the Royal College of Surgeons in Dublin; and if any person shall, after the passing of this Act, assume the name or style of a Physician or Surgeon, without being entitled to do so as aforesaid, he shall, on conviction before any Magistrate having jurisdiction in the county, city, or place where the offence was committed, forfeit and pay a sum not exceeding five pounds, nor less than forty shillings, for every such offence, to be recoverable within three months next after the commission of the said offence.

XXIII. Registered Persons Entitled to Charge for Advice and Visits.—That all persons who shall be registered and possess certificates according to the provisions of this Act, shall be entitled to demand and recover in any Court of Law, with full costs of suit, reasonable charges for medical or surgical advice, visits, and medicines, rendered or supplied by them to their patients, without any other licence than such registry and certificates.

XXIV. None but Registered Persons to Recover Charges.—That after the first day of February, one thousand eight hundred and fifty three, no person shall be entitled to recover any charge in any Court of Law for any medical or surgical advice, attendance, or for the performance of any operation, or for any medicine prescribed, administered, or supplied by him, unless he shall prove upon the trial either that he is in possession of a certificate in force, according to the provisions of this Act, or that he was legally practising in the capacity in which he claims such charge at the time when the debt was incurred.

XXV. Persons not Possessing Certificates Incapable

of Acting as Medical Officers in Public and Other Situations.—That, after the first day of February one thousand eight hundred and fifty-three, no person who does not possess a certificate in force, according to the provisions of this Act, shall be capable of holding any appointment in any part of the United Kingdom, in the capacity of a physician, surgeon, apothecary, or other medical officer, in any hospital, infirmary, dispensary, lunatic or other asylum, lying-in hospital, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse, or poorhouse, parish, union, or other public establishment, body or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age.

XXVI. Summary Penalty against Unregistered Practitioners.—That, if any person shall, after the first day of February one thousand eight hundred and fifty-three, act or practise as a physician, surgeon, apothecary, or licentiate in medicine, surgery, and midwifery, in any part of the United Kingdom, without being duly registered according to the provisions of this Act, and without having a certificate as aforesaid in force at the time of his so practising or acting as a physician, surgeon, apothecary, or licentiate in medicine, surgery, and midwifery, he shall, on conviction before any magistrate having jurisdiction in the county, city, or place where the offence was committed, forfeit and pay a sum not exceeding five pounds, nor less than forty shillings, for every such offence, to be recoverable within three months next after the commission of the said offence.

XXVII. Expulsion of Registered Practitioners for Disgraceful Conduct, or Irregular Practice.—That, if three registered practitioners shall at any time complain to the Medical Council of any part of the United Kingdom, or to the Council of any College or other governing body, that a person who had obtained his licence, diploma, or qualification from such Medical Council, College, or body, had been conducting himself in a manner calculated to bring scandal and odium on the profession, by publishing indecent advertisements or pamphlets, or immoral or obscene prints or books, or had been guilty of any other disgraceful and unprofessional behaviour, or of any irregular practice, the said Medical Council, Council, or other governing body aforesaid, are hereby empowered to cite the person accused before them, first giving him due notice, and a full statement of the charges against him; whereupon the said Medical Council, Council, or other body, having heard the defendant, and on being satisfied that the charges have been proved, or in default of his appearance, having decided that the charges have been proved, they are hereby required to erase the name of such person from the books or rolls of the said Medical Council, College, or other institution, as the case may be, and shall transmit forthwith to the registrar of that part of the kingdom to which such Medical Council, College, or other institution belongs, an official report of their decision, authenticated by the seal of such Medical Council or College; and the said registrar shall thereupon strike out the name of

the offending party from the register in his custody, and it shall ever afterwards be excluded from every register to be kept under the provisions of this Act, unless the Medical Council, Council, or other governing body by whom the name was first erased shall re-admit it into the books or rolls of such Medical Council, College, or other institution. Provided always that the name of no person who may be possessed of a licence granted by a Medical Council according to the provisions of this Act, shall be erased from the register, unless the registrar receive from such Medical Council an official decision to that effect, authenticated by their seal.

XXVIII. *Penalty for the Wilful Falsification of the Record of Certificates by any Registrar.*—That if any Registrar under this Act shall wilfully make or cause to be made any falsification in any matters relating to any register, certificate, or record aforesaid, every such offender shall be deemed guilty of a misdemeanour in England and Ireland, and in Scotland of a crime and offence; and shall, on conviction thereof, be sentenced to be imprisoned for any term not exceeding six months.

XXIX. *Penalty for Obtaining Certificate by False Representations.*—That if any person shall wilfully procure or attempt to procure a certificate from any Registrar, by making or producing, or causing to be made or produced, any false or fraudulent representation or declaration, either verbally or in writing, or shall, by any false or fraudulent means whatsoever, possess, obtain, use, or attempt to possess, obtain, or use, any certificate as aforesaid, every such person so offending, and every person aiding and assisting him therein, shall, upon being convicted thereof, be adjudged guilty of a misdemeanour in England and Ireland, and in Scotland of a crime and offence; and thereupon it shall be lawful for the Court before whom such offender shall be tried and convicted to sentence such offender to be imprisoned, with or without hard labour, for any period of time not exceeding six calendar months.

XXX. *Penalty for Falsely Pretending to be a Medical Practitioner.*—That every unregistered person who shall wilfully and falsely pretend to be, or take or use the name or title of, a physician, doctor, bachelor of medicine, surgeon, or apothecary, or any name, title, addition, or description, implying that he is registered under this Act, or that he is recognised by law as a physician, or surgeon, or apothecary, or a practitioner in medicine or surgery, shall, on being convicted of every such offence, before any Magistrate having jurisdiction therein, pay a sum not exceeding ten pounds, nor less than forty shillings, to be recoverable as hereinafter described.

XXXI. *How Penalties are to be recovered; if not paid, the Offender may be Committed.*—That any Justice of the Peace acting in and for the county, city, or place in which the offence has been committed, or any Magistrate appointed by virtue of an Act passed in the second and third years of the reign of Her Majesty Queen Victoria, intituled "An Act for Regulating the Police Courts of the Metropolis," or one of the Justices of Peace Courts in Scotland, may hear and deter-

mine any complaint charging any person with practising medicine, without a certificate, as aforesaid, on the oath of one or more witnesses, or by the confession of the accused party, and shall award the penalty or punishment herein provided for such offence; and in every case of the adjudication of a pecuniary penalty under this Act, and of non-payment thereof, it shall be lawful for the said Justice or Magistrate to commit the offender to any gaol or house of correction within his jurisdiction, for a term not exceeding one calendar month, when the sum does not exceed forty shillings, and for a term not exceeding three calendar months when the sum does not exceed ten pounds, the imprisonment to cease on payment of the sum due.

XXXII. *Application of Penalties.*—That any sum or sums of money arising from conviction and recovery of penalties for offences committed against the authority and provisions of this Act, shall be paid to the Medical Council for that part of the United Kingdom in which such conviction shall take place.

XXXIII. *Examiners may take Candidates to Hospitals, &c.*—That each of the said Examining Boards, or any members or member thereof, shall be empowered to attend with the candidates for licences in the public hospitals, or other public institutions containing sick and diseased persons, and also in any workhouse, with the view of ascertaining the practical knowledge of such candidate in the science of medicine.

XXXIV. *Act not to deprive the Colleges of Physicians in London, Edinburgh, and Dublin, nor the Colleges of Surgeons of England, Edinburgh, and Dublin, of the privilege of conferring Degrees and Diplomas.*—That not anything in this Act contained shall deprive the Royal College of Physicians in London, the Royal College of Surgeons of England, the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the King's and Queen's College of Physicians in Ireland, or the Royal College of Surgeons in Dublin, of their respective rights to grant degrees or diplomas in medicine or surgery; but such degrees and diplomas shall not, after the first day of February, one thousand eight hundred and fifty-three, confer on any person possessing them, or either of them, the right to practise as a medical practitioner in any portion of the United Kingdom.

XXXV. *Provision for existing Students.*—That it shall be lawful for the said several Medical Councils to make regulations for dispensing with such provisions of this Act as to them shall seem fit, in favour of Medical Students who shall have commenced their professional studies before the passing of this Act.

XXXVI. *Act not to affect the Trade or Business of Chemists and Druggists.*—That not anything in this Act contained shall extend, or be construed to extend, to prejudice or in any way affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing and vending, drugs, medicines, and medicinal compounds, wholesale or retail, without the giving of medical or surgical advice.

XXXVIII. *Registered Medical Practitioners exempted from serving on Juries, Inquests, &c.*—That every person

who shall be registered and possess a certificate in force, under the provisions of this Act, shall be exempt, if he shall so desire, from serving on all juries and inquests whatsoever, and from serving all corporate, parochial, ward, hundred, and township offices, and in the Militia, and that the name of such person shall not be returned in any list of persons liable to serve in the Militia, or in any such office as aforesaid; and no person shall be entitled to such exemption as aforesaid, on the ground of being a physician, surgeon, apothecary, or licentiate in medicine, surgery, and midwifery, who does not possess such certificate then in force as aforesaid.

XXXIX. For certain Offences, names of Medical Practitioners to be erased from the Register.—That if any registered medical practitioner shall be convicted in England or Ireland of any felony, or in Scotland of any crime or offence inferring infamy, or the punishment of death or transportation, or if it shall be found, by the judgment of any competent court, that any such medical practitioner shall have procured a certificate under this Act by any fraud or false pretence, or that any such medical practitioner has wilfully and knowingly given any false statement, evidence or certificate, in any case in which by law the evidence or certificate of a physician, surgeon, apothecary, or licentiate in medicine, surgery, and midwifery, is required, the registrar of each of the Medical Councils, on the production before him of an office copy or extract of the conviction or judgment of the court, duly certified under the hand of the proper officer of the Court, or other proof thereof, shall cause the name of such medical practitioner to be erased from the register; and every person whose name shall have been so erased after such conviction or judgment as aforesaid, shall thereby forfeit and lose all the privileges of a registered medical practitioner provided by this Act.

SCHEDULE (A).

Declaration required of a person who claims to be registered as a medical practitioner upon the ground that he was in practice as a medical practitioner before the first day of August, 1851:—

To the Registrar of the Medical Council for England.

I, [Samuel Baker,] residing at [6, Duke Street, Exeter,] in the county of [Devon,] hereby declare that I was practising as a medical practitioner, at [16, George Street, Hastings,] in the county of [Sussex,] before the 1st day of August, 1851.

(Signed) [SAMUEL BAKER.]

Dated this [6th] day of [November] 1852.

SCHEDULE (B).

Licence to Practise Medicine, Surgery, and Midwifery.

This is to certify that [Herbert Jones] has been carefully and deliberately examined as to his skill and abilities in the science and practice of medicine, surgery, and midwifery, and as to his fitness and qualification to practise the same, by the Examining Board appointed in pursuance of an Act of Parliament passed in the [] year of the reign of Her Majesty Queen Victoria, intituled “An Act to produce Uniformity of Medical Education and Qualification, and for the Registration of those licenced to practise in Medicine;”

and the Medical Council for [England] have, by virtue of the powers vested in them by the said Act, directed this Licence to be granted to the said [Herbert Jones,] certifying that he is duly qualified to practise medicine, surgery, and midwifery.

(Signed) [JOHN FAIRBROTHER,]
President of the Medical Council for [England.]

(Signed) [HENRY BROWN,]
Registrar of the Medical Council for [England.]

Dated this [3rd day of [March], 185 .

SCHEDULE (C)

The Medical Register for [England].—Medical Registration Certificate for 185 .

In accordance with the provisions of an Act of Parliament, passed in the [] year of the reign of Her Majesty Queen Victoria, intituled, “An Act to produce Uniformity of Medical Education and Qualification, and for the Registration of those Licenced to Practise in Medicine,” I hereby certify that [James Howard], residing at [No. 15, Ormond Street, Manchester], in the county of [Lancaster], (having produced, before me, the Diploma of [the Royal College of Physicians of England] granted to him [April 18th, 1840], as [a Fellow of that College],) or, (having signed, before me, a Declaration according to the form in Schedule (A) to the said Act annexed) or (having produced, before me, the Licence of the Medical Council for [England] granted to him the [4th] day of [May] 185 ,) he has been duly registered, according to the provisions of the said Act, as a person who is qualified to practise Medicine in any part of [England and Wales], and that he is entitled to exercise all the powers and privileges conferred by the said Act.

This Certificate to remain in force until the 1st day February, 185 , and no longer.

(Signed) [HENRY BROWN,]
Registrar of the Medical Council for [England].

Dated this [1st] day of [February] 185 .

SCHEDULE (D).

The Medical Register for [England], consisting of the names and places of residence (arranged alphabetically), with a description of the qualifications, and the dates thereof, of all persons legally qualified to practise medicine in [England], in the year 185 .

The Names of Registered Medical Practitioners, (arranged Alphabetically.)

NAMES.	Qualifications and their Dates.	Places of Residence.
ADDISON, JAMES	Diploma as a Fellow of the Royal College of Physicians of England, dated 9th August, 1836	No. 16, Tudor Street, Manchester.
ADLARD, HUGH	Licence from the Medical Council for England, dated 3rd April, 1853	No. 7, Milton Street, London.
ADNEY, RALPH	Declaration, as required by law, of having practised as an Apothecary before the 1st day of August, 1851	The Grove, Camberwell.
ADPART, EDMUND.	Licence of the Society of Apothecaries, London, dated 11th June, 1834	No. 40, Tolville Street, Leeds.
ADWIN, GILBERT	Licence from the Medical Council for England, dated 2nd May, 1853; Diploma as a Member of the Royal College of Surgeons of England, dated 5th July, 1854.	No. 19, Milsom Street, Manchester.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

SEPTEMBER 4TH, 1851.

T. W. WILLIAMS, ESQ., IN THE CHAIR.

Non-Vascular Polypoid Tumour of the Rectum removed by Operation.—By Mr. HILL.

THE subject of this case was a woman, aged 51. The symptoms of the disease could not be traced further than five months ago, when she began to complain of burning in the rectum, and a slimy discharge soon afterwards appeared, and became very troublesome to the patient. Five weeks before the operation, portions of the tumour projected from the anus. She then suffered from constant tenesmus and discharge, and her health began to fail. In the operation the tumour was found to be attached to the posterior wall of the rectum, for about one quarter of the circumference of the gut, and extended from the anus to the height of four or five inches. The necessary examination brought on violent straining, and after the skin had been divided, a blunt hook was readily inserted, and the tumour was drawn out of the intestine, and its remaining attachments divided. It was little organised, and scarcely bled when torn by the hook. It was divided into two lobes, and was covered with thickened mucous membrane. Its substance was homogenous, tore readily, and was of a blackish brown colour.

Fibro-Cartilaginous Tumour beneath the Angle of the Jaw.—By Mr. HILL.

It was removed by operation from a healthy girl, aged 22, chiefly for the sake of appearance. It was situated against the body of the lower jaw, sinking below it, and coming in contact with the submaxillary gland. The platysma was stretched over it, but it had no further important attachment than its connection with the gland by dense cellular membrane, and when the skin and platysma had been divided, turned out, and was readily removed. It had been forming five years. It was the size of a hen's egg, though of greater transverse diameter. When divided, the cut surface presented a very close resemblance to the tissue of a turnip. It was very dense and firm; hardly any fluid could be expressed. It seemed made up of a pearly, semi-transparent, opaque white substance, in nearly equal proportions, disposed without any definite arrangement. There was entire absence of any of the white fibrous lines of scirrhus.

Examined under the microscope by Dr. Russell.—

It had exactly the characters of *fibro-cartilage*, containing an abundance of cells, set in a firm, transparent, intercellular substance, at regular intervals, and was crossed in all directions by fibrous striation. None of the cells floated loose, but all were firmly connected by the intervening tissue, none being in contact. They all contained good-sized nuclei.

Uterus, Fallopian Tubes, and Ovaries of a Prostitute.—

By Mr. HOARE.

The parts exhibited were removed from a young woman who died suddenly of heart disease. She led the life of a prostitute, and was addicted to spirit drinking. The cavities on the right side of the heart were dilated, and their walls thin. Some miliary tubercles were scattered through both lungs. The fallopian tubes were infiltrated and distended with a white cheesy matter, (tubercular,) as thick as a finger, hard, and tortuous. There was no appearance of healthy mucous membrane, but it was softened and yellowish; the outer coat was thickened and hard. Near to the left ovary the tube was distended into a tumour, of the size of an egg, its contents being of the same nature. At the posterior part of the uterus lymph had been deposited, and become organized.

OCTOBER 2ND, 1851.

W. H. PARTRIDGE, ESQ., IN THE CHAIR.

Pelvic Abscess communicating with the Rectum and Bladder, and opening also externally: suddenly fatal by Ulceration into the External Iliac Artery.—By Dr. ELKINGTON.

E. WYER, aged 29, was admitted into the Lying-in Hospital, September 10, 1851. She stated that she had been married nine years, and had had one child, which was eight years old. About last Christmas she had an attack of acute rheumatism, to which she had been subject for several years in the upper and lower extremities. In February, and soon after the rheumatic inflammation had left the extremities, she suffered an attack of pain in the pelvis and hips. This was followed by a purulent discharge from the vagina, but without any permanent relief. She has been in a bad state of health ever since, and suffered almost constant and severe pain. Has had great pain, and, at times, difficulty in making water. Lately her urine has escaped every now and then, involuntarily, and has been at times mixed with pus. She is much emaciated; pulse quick and feeble; no hectic. Complains of great pain and tenderness over the lower part of the abdomen and constant inclination to bear down.

On making an external examination I found a fulness of the right iliac region, and immediately above Poupart's ligament, and midway between the anterior superior spine of the ilium and pubes, an oval swelling, nearly two inches long, the integuments covering it being thin, red, and about to ulcerate. There was fluctuation, but the pain on pressure was so great, over the whole of the lower part of the abdomen, that it was impossible to make a careful and minute examination.

On making an examination per vaginam, the uterus appeared about its normal size but was drawn upwards, the vagina relaxed, and its surface, anteriorly, puckered or irregular, and thickened. She gets very little sleep. Ordered Pil. Anod. omni nocte. Mist. Tonic. ter die. A warm linseed poultice and a generous diet. The poor woman became alarmed at her state and left the

hospital on the 12th. She returned, however, on the 15th. She was worse, and the swelling in the groin larger. In the course of the night the abscess broke, and there was a large quantity of very offensive pus discharged. She had previously refused to allow the abscess to be opened. She was directed to lie upon the right side to facilitate the escape of the pus, to continue the poultice and her mixture and pill, and to take a pint of porter and two glasses of port wine daily.

On the 21st of September she was better, had less pain, and less discharge. During the night she got out of bed, and soon after she had lain down again, she called to the nurse and said she was bleeding, and died almost immediately. The nurse states that she lost a pint of blood in two minutes, and that "it came out like a fountain."

Post-mortem examination.—A large cyst was found occupying the right half of the pelvis, its outer wall being bounded by the bones of the pelvis. It communicated by a small opening with the bladder, with the cœcum, and with the external opening in the groin. It appears to have had its origin in the ovary. The integuments about the groin were completely separated from the muscles, which were bared to the extent of two or three inches. The external iliac artery, about an inch below the bifurcation of the common iliac, was opened by ulceration, and its coats for some little distance appeared in a sloughy state. The artery was surrounded for some distance by partly-organized lymph, which firmly connected it with the vein, but at the point of ulceration there was no deposit of lymph nor any attempt at protection or repair.

Monstrosity.—By Mr. BASSETT.

The specimen consists of the lower portion of the body of an infant, consisting apparently of a single extremity, expelled about the full period of gestation. The umbilicus is found issuing from near the median line. Passing downwards and backwards from this point we notice, on the one side, a dark mark, indicating the anal aperture, which was not patent; on the other side, furrows, and a small portion of pendulous integument, as if some intra-uterine amputation had taken place. From the knee the single lower extremity diminishes, until it terminates in a crooked, shrivelled, proboscis. The bones which have been dissected, will be observed as follows:—The spinal column terminates in front of a rudimentary sacrum; this, with the lower part of the spine, is attached to the innominate bones, which consist merely of the ilia, coalescing to form a single, irregular, fan-shaped bone, terminating in front in a sharp point; the true pelvis is, consequently, quite deficient. The femur presents a large head. Two great trochanters on opposite sides of the bone; a small shaft, the lower end expanded into two pairs of condyles, separated by a broad groove. The periosteum is detached. A quantity of dark coloured fluid was found between it and the shaft of the femur, as also in the knee-joint. There are two patellæ adapted to each pair of condyles. Below the knee a single tibia only is found, which terminates in a point. The muscular

development is irregular. No urinary bladder was observed. The genitals were entirely absent. The bowels were naturally developed, and were full of healthy-looking meconium. All the other parts of the child healthy.

From the mother's statement the child appeared to have been dead about ten days. She had been the subject of no peculiar mental impression; but from having perceived so little of the child, she thought "something was wrong." She afterwards informed me she had frequently noticed, and regarded with feelings of pity, a man who had lost one of his legs, but she never felt any fear.

Large Bony Tumour Connected with the Pelvic Bones, lying partly in, and partly projecting through, the Pelvis and Thyroid Foramen.—By Mr. SAVAGE, West Bromwich.

Mr. B., aged 58, of strumous habit, a saucepan-handle maker by trade, was seized with acute rheumatism in February last, after a continued exposure to wet and cold. The attack was a very severe one, and after a time became chronic. He so far recovered as to be able to get down stairs in April. About this time he began to complain of severe pain over the sacrum, no tenderness, and considerable difficulty in walking, his general health remaining very bad. By my advice he had change of air, and went to the salt wells near Dudley, and had several warm baths, with the hope of relieving the pain in the back and the general stiffness about the joints. After staying a fortnight, he came back worse than he went, with loss of flesh, impaired appetite, profuse sweats, increased pain in the back, which he described as being internal, (it was unaccompanied by external tenderness,) and an entire inability to walk; there were several strumous enlargements about the ribs, the whole inguinal glands became enlarged and tender, and a small hard tumour, pushing itself down under the adductor muscles of the thigh, made its appearance; the fæces became somewhat flattened; a frequent desire to make water. The tumour in the thigh increased rapidly, eventually becoming as large as the doubled fist; and the upper extremity pushing the bladder above the pubes; he was now unable entirely to empty the bladder, and I was obliged now and then to pass the catheter. He gradually got worse, emaciated very much, and died in the latter part of August.

On making a *post-mortem* examination, thirty-four hours after death, the body was found to be extremely emaciated, enlargements on about half a dozen of the ribs, and the inguinal glands enlarged. I was only allowed to examine the region of the tumour; and in order to expose the contents of the pelvis well, I made a semilunar incision from the superior anterior spinous process of one ilium to the other, and on the right side joined this to another extending by the inner side of the sac round the tumour; these gave us a complete view of the contents of the pelvis and the projecting part of the tumour. The bladder was found

thickened on its under surface, arising from pressure of the tumour, otherwise healthy; ureters natural, kidneys healthy. The anterior surface of the rectum was adherent to the posterior part of the tumour, which three parts filled up the cavity of the pelvis, and was firmly attached to the rami of the pubis and ischia. It had projected into the thigh, through the obdurator foramen; it was connected with the bones of the pelvis, apparently by the periosteum. On section, it was found composed of cancellated bony tissue, which was covered externally by a layer of compact tissue.

Cancerous Tumour connected with the Stomach.—By Mr. SAVAGE, West Bromwich.

Mary Ann H., aged 52 years, married, the mother of four children, of thin spare habit of body, had an attack, about two years ago, of inflammation of the liver; since then she has been subject to dyspepsia in various forms, and in March last had another of her attacks of inflammation of the liver in the acute form; this was relieved by leeching, blistering, and mercury, leaving an enlargement and hardness over the liver. After a little time both these symptoms increased, accompanied by tenderness and low fever, with a doughy feel of the part, giving an idea of abscess of the liver forming. General peritonitis afterwards came on, which was met with the usual treatment; ascites afterwards supervened, and in April last I tapped her, and drew from her nineteen pints of serum. After this she somewhat rallied, and was able to get down stairs again, the swelling and hardness of the liver still continuing, rather increasing in size, accompanied at times with great pain, and some tenderness generally over the abdomen. Her secretions were generally natural, and her appetite failed. She became emaciated, and finally sunk in the early part of September.

On making a *post-mortem* examination about fourteen hours after death, the body presented externally extreme emaciation, with great hardness and enlargement over the liver, and some fluctuation was felt in the abdomen. On opening the abdomen, about two quarts of serum escaped from the cavity of the peritoneum; the right side over the liver was occupied by a large substance, strongly adherent to the walls of the abdomen, and extending over the transverse colon, duodenum, and large curvature of the stomach, to all of which it was strongly adherent; it had the appearance of scirrhus; the liver was enlarged, softened, and presented the nutmeg appearance; the intestines were generally pale throughout; the spleen and pancreas both healthy; the whole of the contents of the abdominal and pelvic viscera were strongly adherent throughout, and thickly studded over with tuberculous deposit; the kidneys were healthy; the examination was not carried further.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—We are instructed by the Committee of the Manchester Medico-Ethical Association, to forward to you the accompanying correspondence for publication in the *Provincial Medical and Surgical Journal*.

Having in a previous instance of the same kind remonstrated with Mr. Windsor without any success, the Committee consider that they have no other means of dealing with the case, than by bringing the facts to the knowledge of the whole profession.

We are, Sir,

Your obedient Servants,

JOHN AIKENHEAD, } Hon. Secs.
W. C. WILLIAMSON, }

112, Oxford Street, Manchester,
December 27, 1851.

CORRESPONDENCE.

Manchester, Piccadilly, December 24, 1851.

DEAR SIR,—I forward to you the enclosed correspondence, which, as one of the Secretaries of the Medico-Ethical Association, you will deal with in the manner you deem best. The statements contained in Mr. Windsor's last communication I know to be incorrect. He has been misinformed. The facts are precisely as stated in No. 7 of the series. I felt, however no necessity of replying further, as their bearing is purely personal, not professional. On every other ground but this latter one, I should have treated Mr. Windsor's conduct with contemptuous disregard. I am sure that in this case you will, on Mr. Windsor's account, feel with me more of sorrow than of anger. Yet, when such flagrant infractions of professional morality, as those disclosed in the accompanying correspondence, obtain with a practitioner of forty years' standing, an Honorary Fellow of the College of Surgeons, and Senior-Surgeon to an hospital, I think it becomes a duty to notice such conduct, in some form or another; and it is in this view of the case that I send you the correspondence.

I am, dear Sir, yours faithfully,

Dr. Aikenhead.

DANIEL NOBLE.

No. 1.

Piccadilly, Sunday afternoon.

DEAR SIR,—Last evening I was sent for to see Mrs. —, of — Road, after being with whom for nearly an hour, I prescribed and left word that I should call again early this morning. I had already told them I could not recognise or in any way act with the previous attendant, who I understand possesses no qualification for the duties he has undertaken, nor the title he has assumed. I have to-day received an intimation that my further services are dispensed with, because you, less scrupulous than myself, see no difficulty in sanctioning, and in co-operating with, the person I had declined to meet; and, in fact, that you had entered upon an attendance under

the circumstances in question. I do not complain of this conduct in reference to myself; I ask for no explanation; but I deem it right that you should not be unacquainted with any of the circumstances of the case, and I regret exceedingly that so flagrant a disregard of the first principles of medical ethics, should have been shown by you, one of the oldest and most successful members of the profession in Manchester.

Yours truly,

J. Windsor, Esq.

DANIEL NOBLE.

No. 2.

Piccadilly, Sunday evening.

DEAR SIR,—I have just received your note, and am sorry that anything should have occurred unpleasant to yourself. The circumstances are these:—After I had gone to bed late last evening, I received an urgent message to visit Mrs. —, of — Road. On arriving there, I found Mr. Hughes in attendance at the house, that he had attended her in her confinement about a week previously, and had subsequently been in regular attendance. I knew nothing of your attendance until I had been some time in the house, when I was informed of it, and your prescription was shown to me. You had prescribed, I believe, Tra, Opei. Sp. Ammon. Foetid, and Mist. Camph., but I am not quite certain, and I was informed of your having stated to the family that you did not consider the case as one of any danger. I must confess that I had a very different impression of it, and cannot but suppose that it must have considerably changed its character in the interval of our respectively seeing it. She had been wildly delirious, with screaming and restlessness, her pulse 130 a minute, and of a strong and bounding character. Under these circumstances, though I should have been truly glad to have done so, I could not sanction the immediate propriety of your prescription. Although I had not had any professional or other communication with Mr. Hughes for a very long period, I knew nothing, whether or no, he had yet become a qualified practitioner. I stated my opinion of the case to him, and that the only safe treatment of it should be at once actively and decidedly antiphlogistic. Though I found her rather better this morning, and by no means out of danger, I am of opinion that any other plan of treatment than the one I thought right to suggest, would have involved the greatest risk of her life, and I could not, under the circumstances, conscientiously decline interfering, as otherwise I should have been glad to have done.

Yours truly,

D. Noble, Esq.

J. WINDSOR.

No. 3.

Piccadilly, Monday morning.

DEAR SIR,—Permit me to ask you, with the respect due to one so much my senior as yourself,—Whether a difference of opinion concerning a case, constitutes a sufficient reason for setting aside a regular practitioner and taking up with one notoriously disqualified? I do not complain that your *opinion* was different from mine, but of the *conduct* which ensued. I submit that you should have procured my personal attendance once more, ignoring the person you consulted with; when, if I had failed to convince you that the prominent features of

the case were hysterical and adynamic, rather than inflammatory, or contrariwise, it would have been for one of us to retire by common consent, unless a third had been called in to reconcile our differences or to give preponderance to the opinion of one of us. I only regret this circumstance on personal grounds; had it occurred with one to whom I was a comparative stranger, I never should have noticed it. That *you* should so have acted is yet past my comprehension.

Yours truly,

J. Windsor, Esq.

DANIEL NOBLE.

No. 4.

15, Piccadilly Dec. 22nd, 1851.

DEAR SIR,—I received your second note this morning, but considering my former reply sufficiently explanatory, I have little to add. I consider the case of Mrs. —, to which I was called up after midnight, to be one of a very dangerous character, requiring very prompt and active remedial means. I have seen her twice since, and have yet observed nothing inducing me to alter my first impressions. Your own, both as stated at the time, and since in your note to me, appear to have been very different, and I could only explain this as stated before, by some change in the interval elapsing between our respective visits; and as Mr. —, decided upon retaining me, although the choice was freely offered to him, as I had no wish to supersede you, and should have been glad not to have been called in at all, I submit that under the circumstances I was not only justified in doing so, but imperatively called upon to prescribe. You mentioned that you considered it a case of anæmia combined with hysteria, but since my attendance she has exhibited no symptoms of either the one or the other, but pretty unequivocally those of puerperal mania.

Both the patient and her husband, I am informed, had long been particular acquaintances of Mr. Hughes, who was very anxious about the case, and suggested my advice upon the occasion, which I have endeavoured to give, at least, conscientiously, and, if I could have helped it, without offence to any one.

Yours truly,

Daniel Noble, Esq.

JOHN WINDSOR.

No. 5.

Piccadilly, Monday evening.

DEAR SIR,—Please to refer again to my second note, and you will find that I say nothing of anæmia; *adynamic* was the word I used. *Ataxic*, probably, is the term which would best have conveyed my idea. I, too, deemed the case to be one of "puerperal mania," and by that very term have entered it in my case-book. But I need not remind you that the phraseology is applicable to very different pathological conditions, as with mania occurring under other circumstances.

My previous remarks upon Mrs. —'s case, have had reference to the state of her system as demanding treatment; and considering that it bore an affinity rather to the hysterical and adynamic condition, than to that of inflammatory action, I prescribed the remedies, which do not appear to have met with your approval. I never said that there was no danger, but that the patient was not *dying*, as the bystanders imagined.

But, once more, I must urge upon you, that about any difference of opinion, or any question of personal grievance, I repudiate all concern. My complaint is, of the grave offence which you have committed against the profession to which we respectively belong, and I must really insist, that the actual point at issue you entirely evade.

I presume that this most unpleasant correspondence must now close. I think it right, however, to inform you, in conclusion, that I purpose placing it in the hands of the Secretaries of the Medico-Ethical Association, remaining meanwhile,

Yours truly,

J. Windsor, Esq.

DANIEL NOBLE.

No. 6.

Piccadilly, Tuesday afternoon.

DEAR SIR,—I received your third note this morning, and, in conclusion, will make a few observations, chiefly as a brief recapitulation of the whole affair. It appears that you were called on Saturday evening to visit a patient who had been attended in her confinement, and subsequently for about a week, by Mr. Hughes, but you did not choose to recognise him in the matter, but by yourself prescribed for the patient; that, in the course of the same night, I was sent for, and after visiting Mrs. ———, I was, for the first time, informed that you had also seen her, and your prescription was shown to me. Having particularly examined the symptoms, and inquired into the previous condition, (one of great excitement with delirium,) and a very frequent, strong, bounding pulse, I did not feel justified in then adopting your plan of treatment. I can sincerely add, that I thus differ from you with very great reluctance, and should have been very glad to have either concurred with you, or to have given up the case altogether, if I could have done so with propriety, but considered that my professional duty to one placed under my care, should be paramount to every other consideration. In your note to me you mentioned that you considered the case one of an hysterical and adynamic nature, (I had certainly misread the latter word *anæmia*), and had from the first considered it as puerperal mania. I was informed that you had pronounced it to be unattended with any particular danger, and on further inquiry to-day your observation to that effect has been reasserted. I, on the other hand, considered it a case of very urgent character, and fraught with the most imminent danger. With regard to my conference with Mr. Hughes, the regular attendant in the case, which you seem to consider the gravest part in the matter, I must frankly acknowledge that I saw no objection in receiving from him, one who had gone through a regular professional education, though not yet possessed of a diploma, the history of the case, and the treatment hitherto pursued.

On the day following my first visit I might have called upon you, to explain verbally, the circumstances which had occurred, but was excessively hurried, as, indeed, I have been ever since, and your first note on Sunday evening seemed to supersede that, perhaps, more satisfactory mode of explanation.

Yours truly,

Daniel Noble, Esq.

JOHN WINDSOR.

No 7.

Piccadilly, Tuesday evening.

DEAR SIR,—Respecting the *pathology* of Mrs. ———'s case, I will enter into no dispute, the greater your difference of opinion with me, the more weighty, I maintain, were the reasons for your requiring my attendance in consultation, before you offered an opinion, or prescribed. I have only this afternoon been informed, upon unquestionable authority, that the family did not call you in at all, but the irregular practitioner before referred to; that Mr. ——— knew nothing of your coming until he saw you in his house in company of the person who had been virtually dismissed; that, upon learning the immediate antecedents, you asked to see my prescription, and, upon its being shown, pronounced at once a decidedly unfavourable judgment upon what I had done. Is it wonderful that, upon this, you should have been chosen to continue in charge of the case—you, upwards of twenty years my senior? If you see nothing objectionable in the practice of meeting in consultation persons unqualified, you are simply at issue with the worth and respectability of the whole profession.

Yours truly,

J. Windsor, Esq.

DANIEL NOBLE.

No. 8.

Piccadilly, Tuesday evening.

DEAR SIR,—I have received your note this evening, and although I intended my last to you to be a concluding one, I am induced by yours to add one or two remarks. I have had an opportunity since receiving it of making some inquiry, and am assured that Mr. Hughes had the sanction both of Mr. ——— and other parties before I was sent for. I was also informed, at the same time, that your own visit was not known to the family before you arrived; that, from the great suffering of the patient, the opinion of Mr. ———, druggist, had been asked, and he, of his own accord, had sent for you.

In conclusion, I may say, that I choose to make a considerable distinction between those who have been educated regularly, and pursue a regular practice, and those who are mere charlatans, or practise irregularly, as homœopaths, hydropathists, etc.

Yours truly,

Daniel Noble, Esq.

JOHN WINDSOR.

Foreign Department.

FRANCE.

Sanguineous Pelvic Tumours in the Female.

These tumours are formed by extravasation of blood in the sub-peritoneal tissue surrounding the uterus. Their history has already been written by MM. Langier, Bourdon, and Velpeau, who recently brought the subject before the Surgical Society of Paris.

In most cases there are certain precursory symptoms. After some days' illness menstrual disturbance declares itself, such as sudden suppression or menorrhagia, which recurs every three or four days. This subsides,

and is followed by pains in the pelvis, with sensation of weight and bearing down. At the same time the general functions suffer, the appetite is lost, there is frequent bilious vomiting, and obstinate costiveness. The abdomen, if examined after evacuation of the rectum and bladder, is found to be somewhat tympanitic and tender on pressure. A tumour will be perceptible in one or other inguinal region, round, smooth, and indistinctly fluctuating. The finger introduced into the vagina will discover a tumour in the recto-vaginal septum, which gives a sensation of fluctuation, more distinct than that of the abdomen. It generally causes more or less displacement of the uterus, pushing it sometimes so high that the os uteri is beyond the reach of the finger. That the swelling above the pubes is connected with that of the vagina is clearly ascertained by the mobility and fluctuation which is perceived by the alternate movements of the finger in the vagina, and the hand placed on the abdomen.

The progress of these tumours depends upon the course of treatment pursued. If they are opened early the tension of the abdomen declines, the vomitings cease, and the bowels resume a natural action; but if the incision be not sufficiently free fresh accumulations take place, and the relief is but partial. M. Viques, who has published the above remarks, (*Theses de Paris, 1830.*) advocates the early puncture of the tumour in the vagina, with a large sized trocar, and the frequent use of injections of warm water, to facilitate the expulsion of the coagulated blood.

The etiology of these tumours is very obscure. They occur during good health, and in robust as well as in feeble women. The author considers it most probable that they are connected with the ovarian congestion which occurs at the catamenial period.

Treatment of Lepra and Psoriasis.

M. Cazenave has published some observations on the successful treatment of lepra and psoriasis by sesquicarbonate of ammonia. The dose is about five grains three times a day in some diaphoretic mixture.

Nasal Articulation in Children.

In the *Union Médicale* M. Trousseau speaks of an affection to which children are subject, which is principally characterised by a nasal intonation of the voice. The complaint frequently dates from an antecedent attack of angina, with difficulty of swallowing, and often leads, at first sight, to the suspicion of imperfection in the palate. The chief appearances found on inspecting the throat are patchy congestion of the pharynx, enlarged tonsils, and pendulous uvula, which latter the author believed to be due to a species of paralysis. His treatment consists in the topical application of the nitrate of silver.

Pyelitis followed by Renal Abscess during Pregnancy; Nephrotomy; Urinary Fistula.

M. Reimoneng (*Journ. de Med. de Bordeaux*) narrates the case of a woman, who, after frequently passing gravel for several months in succession, was seized with fever. When seen the pulse was quick, she

had profuse perspiration, frequent vomiting, and had emaciated to a marked degree. On examination of the abdomen two large tumours, were found, separated by a furrow in the median line. That on the right side was solid and of a round shape; that on the left was oval. In the right iliac fossa a distinct intermitting *bruit* was heard *per vaginam*. The neck of the uterus was discovered to be high up, and turned to the left; the os was patulous, readily admitting the tip of the index finger. The patient, who had borne several children, believed herself pregnant, so that little difficulty was found in referring this tumour to the gravid uterus.

But what was the nature of the large tumour on the left side? After due deliberation the author pronounced it to be a renal abscess, the result of calculous pyelitis and obliteration of the ureter. This opinion was based upon the evidence of frequent nephritic attacks, with the passage of concretions prior to the commencement of the swelling.

Having determined to evacuate the abscess which projected in the lumbar region, the potassa fusa was applied, and two days after a bistoury was plunged through the eschar, and gave issue to a large quantity of sero-purulent fluid. After this the abdominal tumour subsided, and the boundaries of the enlarged uterus became plainly defined; at the same time the perspirations diminished, and the woman recovered her health and strength, with the inconvenience only of an urinary fistula in the loins. She was delivered four months subsequently.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

On Impregnation.

Two papers have been read before the Royal Society, having for their object the elucidation of the mysterious process of generation. In one by Mr. Newport, the author has recourse to a new force which he calls *sperm force*, residing in the spermatozoon, to explain the phenomena appertaining to the process. This force is, he thinks, peculiar, and quite distinct from that by which the spermatozoon itself originates and is developed. He also distinguishes it from *muscular* and *nervous* force. In proof of his views he endeavours to show that the spermatozoon has a definite anatomical as well as chemical composition, which differs in different animals. He has ascertained that motion of the spermatozoa is a necessary element in fecundation, as they were unable to impregnate after motion had ceased.

Dr. Henry Nelson studies the same subject in a paper on the reproduction of the *Ascaris Mystax*, a parasite which infests the intestines of the common cat; in which the important fact is noticed, that the spermatozoa gain direct admission into the interior of the ova. In this paper, with reference to the male, the author traces the gradual formation of the semen, its development into a cell, its investment with an envelope, the solution of the latter, and the appearance of granular structure in the nucleus of the seminal cell. The ex-

ternal granules are then seen to coalesce, to form a membrane, which ultimately becomes a curved coecal tube.

In the female the author draws attention to a narrow portion of the coecal extremities of the generative apparatus, which is the oviduct, and the tube in which the ovule encounters the seminal particles. The coecal extremity of the ovary also, according to his observations, throws out a solid particle which forms the germinal vesicle. In watching the application of the spermatic cells to the ovule, as we have stated, he observed distinctly that the spermatic particles became embedded in the vitelline structure. — *Proceedings of the Royal Society*, 1851.

SURGERY.

Tracheotomy as a Remedy for Epilepsy.

A second case, in which tracheotomy has been performed in epilepsy according to the suggestion of Dr. Marshall Hall, has been reported by Mr. Anderson, the results have hitherto proved most satisfactory.

The woman, aged 36, had been epileptic 24 years, and her father had been afflicted in the same manner. The operation was performed three months ago, since which time she has had no formidable access of the disease.

It is satisfactory to be able to state that Mr. Cane's case has been completely successful. The patient, when seen in October, had not the slightest return of epilepsy. The operation was performed in March.

In reference to the easiest way of performing tracheotomy, Dr. Marshall Hall proposes a free incision through the integument, then a separation of the cellular tissue, with a director or other blunt instrument, and lastly to open the trachea with a trocar, the tube of which has a cutting edge. Instead of a tube to breathe through, he proposes an instrument made of wire. — *Lancet*, December 6th, 1851.

MIDWIFERY.

On Laceration of the Perineum and its Treatment.

By Mr. S. B. BROWN.

A paper on this subject has been recently presented to the Medical Society of London. The author classes the accident under four varieties, the first and second being different degrees of rupture of the perineum, without laceration of the muscles; the third consisting in rupture between the sphincter vagina and the sphincter ani, a fissure being thereby formed, through which the author stated the child might, if small, pass. In the fourth, the muscles just named, together with the recto-vaginal septum, were torn, and thus the bowel and the vaginal tube were laid into one. In the first three varieties, drawing off the water frequently by the catheter, close apposition of the thighs, and the application of a suture or two, generally sufficed to cause union of the edges of the wound by the first intention. The last and severest requires a more complicated surgical procedure. The causes of the laceration are said by Mr. Brown to be three.

1. Sudden and violent contraction of the uterus, taking place whilst the os externum is still undilated.

2. An unusually weak and yielding construction of the tissues composing the perineum.

3. Improper and injudicious employment of instruments.

The results of rupture of the fourth variety Mr. Brown stated to be loss to a greater or less extent of the retentive power of the rectum over its contents; deprivation of the natural support offered to the pelvic viscera by the floor of the pelvis, causing great dragging pain from the hips, and sensation of hollowness; prolapsus of the uterus and bladder, the patient being unable to stand or use exertion of any kind.

The obstacles in the way of a cure are, the mobile nature of the structures; the necessity for functional action; the length of time that perfect quiet has to be maintained; the retraction of parts which has usually taken place before the operation has been attempted; the liability of irritation to internal organs; inflammation and sloughing; and the difficulty of regulating the action of the bladder and rectum. — *Reported in Medical Gazette*.

TOXICOLOGY.

A New Test for Mercury.—By ARTHUR MORGAN.

The following seems to be a novel and hitherto undescribed method of detecting the salts of mercury either in substance or solution:—

If a strong solution of iodide of potassium be added to a minute portion of any of the salts of mercury placed on a clean bright plate of copper, the mercury is immediately deposited in the metallic state, appearing as a silvery stain on the copper, which cannot be mistaken, as no other metal is deposited by the same means.

By this method corrosive sublimate may be detected in a drop of a solution unaffected either by caustic potash or iodide of potassium. In a mixture of calomel and sugar in the proportion of one grain to two hundred, a distinct metallic stain will be obtained with one grain, which of course contains 1-200th of a grain of calomel; in like manner 1-400th of a grain of peroxide of mercury may be detected, although the mixture with sugar is not in the least coloured by it.

With the preparations of mercury in the undiluted state, this process acts with remarkable accuracy, the smallest possible quantity of calomel or peroxide of mercury, such as would almost require a magnifying lens to perceive, placed on copper, and treated with iodide of potassium, will give a distinct metallic stain.

The advantages of this test may be briefly stated as follows:—1st. It is a delicate test, inferior only to chloride of zinc and the galvanic test of zinc and gold. 2nd. It is easy of application. 3rd. It requires a very small portion of the substance to be examined—a matter of no small import. 4th. Acting on the insoluble as well as the soluble salts, it obviates the intermediate process of solution. 5th. When it acts its indications are decisive.

As to the disadvantages, the only one which seems tenable is, that although it acts on minute portions, still that must be in a concentrated condition. For instance, though we may detect the 1-1000th of a grain of corrosive sublimate in a drop of water, we cannot

detect it in a drachm, but this may of course be remedied by evaporation.

Now, with regard to the theory of this process, the following seems most satisfactory, that the iodide of potassium forms a soluble and easily decomposed salt with the various salts of mercury,—that is, an iodide soluble in excess of the iodide of potassium.—*Dublin Medical Press*, December 24th, 1851.

Correspondence.

ON THE USE OF KOUSSO.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—Upon looking over some works upon Ethiopia and Abyssinia, I find the following accounts of the Koussou, and have extracted them under the impression that they may be of interest to some of your readers.

The first is taken from "A New History of Ethiopia. By the learned Job Ludolphus, Counsellor to his Imperial Majesty of Saxony, &c." The date of this, the second edition of the English translation, is 1684.*

"There is another Tree which Godignus praises, most excellent against the Worms in the Belly: a Dis temper frequent among the Abessines, by reason of their feeding upon Raw Flesh. For remedy whereof the Habessines Purge themselves once a moneth with the Fruit of this Tree, which causes them to void all their worms."

In the appendix upon natural history, published in 1790, with the large edition of Bruce's travels, there is a minute account of the tree which he calls *Cusso* or *Banksia Abyssinica*.

"The *Cusso* is one of the most beautiful trees as also one of the most useful. It is an inhabitant of the high country of Abyssinia, and indigenous there; I never saw it in the Kolla, nor in Arabia, nor in any other part of Asia or Africa. It is an instance of the wisdom of Providence, that this tree does not extend beyond the limits of the disease of which it was intended to be the medicine or cure."

"The Abyssinians of both sexes, and at all ages, are troubled with a terrible disease, which custom, however, has enabled them to bear with a kind of indifference. Every individual, once a month evacuates a large quantity of worms; these are not the tape-worm or those that trouble children, but they are the sort of worm called ascarides, and the method of promoting these evacuations is by infusing a handful of dry *Cusso* flowers in about two English quarts of *bouza*, or the beer they make from *Teff*; after it has been steeped all night, the next morning it is fit for use. During the time the patient is taking the *Cusso* he makes a point of being invisible to all his friends."

"* * * * * The *Cusso* is planted always near churches, among the cedars which surround them, for the use of the town or village. * * * * * The whole cluster of flowers has very much the shape

of a cluster of grapes, and the stalks upon which it is supported very much like the stalk of the grape. The flower itself is of a greenish colour, tinged with purple; when fully blown, it is altogether of a deep red or purple."

Bruce gives two plates of the tree, and thinks it probable that it may be found in 11° or 12° north latitude in the West Indies or America. He also says:—"It is alleged that the want of this drug is the reason why the Abyssinians do not travel; or if they do, most of them are short lived."

The fact that both these writers allude to the monthly discharge of worms is very curious, and of course founded upon the truth, as they record it independently of each other, at an interval of more than a century, upon their own personal observation; and it is scarcely necessary to add, that if the plant was a cure for worms, there would be no occasion to take it so frequently; and, moreover, if the supply was as plentiful as described, the disease might have been destroyed, supposing it to have been curable by the Koussou.

Recent hospital records, founded upon long experience in this country, have proved that it is a useful remedy, but not more to be relied on as a means of radical cure than many others we have nearer at hand.

I remain, Sir,

Your obedient Servant,

AUGUSTIN RICHARD.

Bristol, December, 1851.

WHAT OUR ASSOCIATION MIGHT DO.

To the Editors of the Provincial Medical and Surgical Journal.

GENTLEMEN,—I am sure that the readers of your *Journal* must have felt highly gratified with the perusal of the very able papers by Dr. Radclyffe Hall, of Torquay. I fear, however, that the excellent remarks and advice which they contain, will not produce the benefit which ought to accrue from them unless they appear in a form better calculated for occasional perusal. Doubtless the efficiency of this great Society, (the Provincial Association) is intimately connected with a proper understanding of the reciprocal duties of its members, and on the unanimity with which they carry out whatever tends to elevate and support the legitimate profession of medicine. As far as I am aware, Dr. Hall's is the first effort to call upon the Association in the way of friendly admonition, to remember its existence as a *collective body*, and bear in mind the capabilities of so large and respectable a number of professional men. The suppression of quackery would be best achieved by attention to such admonition. It is, as Dr. Hall well observes, the *grafting* of irregular practices on orthodox medicine which can alone support such follies; as soon as a broad division is made, they must fall to the ground. To make that division the regular practitioners must be united and firm in discountenancing any connexion whatever with quackery.

I think, moreover, that many medical men would find Dr. Hall's papers very useful for distribution amongst such patients as are willing to receive informa-

* This Ludolphus was the friend and pupil of the famous and learned Abyssinian Monk, Abbaa Gregorius, whose life is shortly narrated as a preface to the work itself

tion respecting prevailing popular doctrines. It is to be hoped, then, that the Association will meet Dr. Hall in the spirit in which his papers are written, and show the importance they set on good counsel, by receiving it with general acclamation. This will be best accomplished by the republication of the papers in question, and the distribution of them throughout the body of the Association.

JOHN BOWER HARRISON, M.R.C.S.E.

Higher Broughton, Manchester,
Dec. 1, 1851.

ON PRIVATE LUNATIC ASYLUMS.

To the Editors of the Provincial Medical and Surgical Journal.

SIRS,—I am the proprietor as well as medical superintendent of a Private Lunatic Asylum, and my attention having been excited by the perusal of some correspondence lately published in your excellent journal, I feel inclined, with your permission, to follow the example of your anonymous contributor, E.B., and make a few observations on a question which has certainly occupied a large share of professional, as well, indeed, as public attention, during the last few years. Indeed, it has more than once occurred to me, that the much abused, maligned, and egregiously suspected class of men, the proprietors of private asylums, might some day feel called upon to take the field in self-defence; but whether that day has opportunely arrived, my judgment is not so clear, and had it not been for the remarks of your able correspondents, I might possibly have watched events a little longer before committing any of my poor reflections to paper. An old writer has somewhere said "that opinion is oftentimes stronger than truth;" and considering that public feeling has been openly, and, it must be admitted, rather hostilely set against proprietors of private asylums, that this feeling has been aroused and is still fanned by eloquence and talent of no ordinary character, I repeat, it is perhaps venturesome in any one of the accused body attempting to enter the lists with such practised and zealous advocates; and besides, when the feelings and passions are more especially engaged, experience tells us that it is only one side of the question which can gain a patient and attentive hearing. And although it may be true that the reign of feeling and passion is apt to be temporary, and will ultimately succumb to the control of reason; yet too long silence might be misconstrued—for silence, says the proverb, becomes the guilty—and too great forbearance might possibly embolden, even to rashness, those who have undertaken to show up our delinquencies.

Fortunately for us, on this, as with many of the great and absorbing questions which have from time to time been debated in the social history of mankind, there are two sides to be considered; and possibly some little sprinkling of truth may be found on both; and as the reformers have long taken pretty exclusive possession of the one, it is very excusable in us trying to make the best of the other, notwithstanding the many disadvantages we labour under in the attempt. But as we are

moderately endowed with the "*mens conscia recti*," we beg to state in *limine*, that we have not the slightest intention to avail ourselves of an appeal to the sympathy "*ad misericordiam*" of those who have belaboured us; on the contrary, we merely invite a few moments' attention whilst we essay to bring under review a few facts, which may at least extenuate the enormity of the crimes with which we are charged; and as your pages might possibly be occupied (although the question is one of decided importance) with matter more generally interesting, we will endeavour to condense our remarks into as concise a form as possible.

And, firstly, we must take up the grand and leading objection, the uppermost, no doubt, in the mind of every member of "The Alleged Lunatic Friend's Society," viz., "private gain." Private gain is asserted to be the great stumbling block in the way of the public securing good and efficient private asylums; and this arises from the temptation it holds out to proprietors to stint their inmates in medicine, food, accommodation, exercise, amusement, or attendance, in order to make a greater profit out of the salary allowed by their friends. Now we are well aware of human weakness, and too often experience it, but we appeal to every reader of your journal, what amount of pure logic is to be found in the above specimen of reasoning? Can the authors of it have even really reflected on the subject at all? Or rather, have they not, after listening to some vociferous orator, or reading at midnight some musty lucubration of the writer in "Household Words," allowed their feelings to become enraptured and carried away by thoughtless enthusiasm, and thus adopted the sentiment on trust? This latter alternative is certainly the most merciful and least reflective conclusion. If we cast them on the other horn of the dilemma, their position seems by no means enviable, for when they affirm that private gain tempts the proprietors to stint their patients in medicine, food, &c., it would have been more satisfactory had they shown at the same time in detail how this cupidity operates. We are, however, left to hypothesis; but we must follow the consequences of their argumentation, and suppose cases for the purpose of elucidating the subject. Let us instance, then, the case of some old gentleman long affected with incurable insanity, and paying a salary at the rate of £200 per annum, he is seized with dysentery; the proprietor of the house, being afraid of a Doctor's bill, and anxious to secure "a large profit out of the salary," allows the poor sufferer to remain in agony for two or three weeks, when death kindly comes to his relief. Thus the proprietor, weak and fond of gain, but ever regardless of calculation, has saved the Physician's fee, but has lost, it may be, £150 per annum.

Alas! what a poor specimen of a stock-jobber. How unqualified "to exercise those acts of duplicity and plausibility so necessary for success in these matters." We will just try the patience of your readers with another instance:—Influenza stalks through the land, invades a private asylum, and through fear of the Physician and Apothecary's fee, four or five of the oldest and most profitable cases are carried off.

But, to proceed no further, I suspect these cases will hardly answer the object intended. Private gain here either sadly miscalculates its own ends, or else our accusers are wrong in some, at least, of their bold

asseverations. Possibly we are unfair towards them; they might never intend to deny that private gain would not sufficiently protect these cases, and secure every remedial aid that was calculated to prolong such profitable lives. It is, perhaps, another class of cases to which they allude, viz., the recent and acute, where medicine is denied to prolong the case. Surely we have hit the right nail on the head now, and I can imagine the whole fraternity of "Members of the Alleged Lunatic Friend's Society" crying out, these are the cases which dwelt in our mind's eye when we made the accusation. We will then endeavour to put the case fairly and justly in review. Here is a temptation too enticing for human weakness:—An acute and profitable case is admitted; private gain at once says,—let the healing balm alone, keep leeches, salts, senna, and nitre from him, and the disease will soon grow inveterate in our hands. We have touched them on one of their strongholds. This impeachment has been plainly and directly made, and its wisdom or folly is involved in a solution of the very important question,—Whether, in the long run, and on the average, it is the interest of a proprietor to cure or confirm the maladies of those who are entrusted to his care. We fear your serious medical readers will hardly await a patient discussion of this point; and with wit and satire we have no wish at present to deal. We may observe that it is an impeachment to which the whole medical as well as legal profession are liable at the hands of calumny, abuse, and ridicule, and we do not think it entitled to any further reply for the present.

In this wise we might proceed with the other items in their thoughtless allegations—*food, accommodation, &c.* "Private gain" suggests, reduce your diet to the lowest possible scale compatible with existence, not knowing, like Pinel, that good diet renders asylums more tranquil and manageable by fewer attendants;—that it leads to much less destruction of property and necessity for restraint;—besides diminishing the mortality to a considerable extent. Further, "private gain" says,—crowd your patients together in small, confined, ill-ventilated apartments;—deny them exercise in the open air;—deprive them of all sources of amusements;—rob them of humane attendants. These simple and no doubt well-meaning men, our accusers, never dreaming of or suspecting the accidents and diseases, and even deaths, which result from such unwise proceedings. It would be easy to amplify these various charges, but such a course would be a work of entire supererogation for "private gain"—the great bugbear of these professing philanthropists, when fully tested and analyzed, seems likely to lead to results entirely different from what they have apprehended. I am ready to admit it is possible, that with some who are pennywise and pound foolish, whose mental vision is very limited and confined, that the desire of private gain may lead to some of the evils suspected and complained of; but it would be paying a very poor compliment to the sagacity and foresight of proprietors in general, to suppose that such treatment is the result of enlightened self-interest. It is very obvious our accusers have been wielding a two-edged sword, but they are answerable for the consequences of their own temerity. They seem to have concluded that the condition and

position of the lunatic proprietor is so peculiar, so special, that the ordinary rules of economy and worldly policy will not apply to them; but we demand of them to explain clearly how it is that those principles of action and conduct which ensure success in general medical practice, will not effect the same ends when exercised in the treatment of lunacy.

In the above observations are evidently embodied many of the views of those who have undertaken the crusade against private asylums, who look upon their existence as a nuisance; and as they are participated in by some well-meaning individuals, they are entitled to consideration. There may possibly exist some little substratum of truth to justify such impressions, but their denunciations have gone too far, and tend to impart the idea to the public mind that all private institutions are to be viewed with the greatest distrust, that they are essentially rotten at the core, and unfit to be trusted with the care of lunatics. Of course, as might be expected, we differ greatly from many of these sweeping conclusions. We have endeavoured to shew that enlightened self-interest is calculated to lead to entirely opposite results to what the reformers affirm; and we are inclined now to assume the aggressive and go a step further, and boldly enunciate the principle that self-interest—in other words, private gain, for the future, constitutes the best safeguard, the surest and only guarantee that the true interests of those afflicted in mind shall be duly and properly attended to. Adam Smith, no mean authority on most points of abstract, as well indeed, as practical inquiry, says:—"That the promptings of self-interest generally lead, in the long run, to the best results; and common sense and experience give much support to this doctrine." But certainly in the eyes of some gentlemen it will be sadly heterodox to attempt to apply such doctrine in justification of private asylums. Now, private asylums have existed, do exist, and despite of all the exertions of the Society, we venture to predict, will continue to exist so long as the principles of human nature continue as they are, and we have confidence that no external influences can easily extinguish them. They are a necessity of the times, created and called into existence by the requirements of civil society, and if properly conducted, under proper and judicious surveillance, they answer a purpose which neither private charity, nor public funds, nor joint-stock companies, will ever supply in this department of the healing art; and the present proprietors of licensed houses, if true to themselves and to the interests of their patients, may take courage, and rest perfectly assured that eleemosynary establishments will not soon supersede them.

Men, especially Englishmen, love freedom in all their actions, and prefer to deal with individuals rather than collective bodies,—enjoy much more the idea of being treated as units than as aggregates; and these feelings, so common to humanity, like the great principle of gravitation in physical science, may be calculated on as always operating and producing their legitimate results.

Let us inquire what proportion of men, with money in their pockets, apply at public hospitals for relief, no matter what talent and skill may distinguish the medical staff; how many employ the union surgeon, no matter what his abilities, but those who have no other resource.

How often do we hear of the club doctor, with a fixed salary, being suspected of apathy and indifference as to the result of his cases. Do not such instances decidedly show that mankind in general prefer to deal with those individuals who practise their profession for private gain, in other words, who are rewarded in proportion to the skill, talent, and industry which they bring to bear on each particular case; for when remuneration is mainly conditional, common experience has taught mankind that greater exertions are put forth, in order that a larger share of it may be realized.

Now, it is immaterial to our present argument, whether these feelings and prejudices have reason and justice for their basis, and our allusion to them does not necessarily pledge us as participators in them; suffice it to say, that we find them in active and constant operation in all such circumstances, and it is very doubtful to us if these suspicions will not operate in a still higher degree in reference to lunatic institutions established on charitable foundations. True, the public will have greater confidence in some of these salaried superintendents than in others, just as they have in some union and club doctors, when these officers happen to be endowed with a larger than ordinary share of humanity, conscientiousness, and industry.

I feel free to admit at once that, in addition to a scientific interest I have in the study of this department of medicine, it is private gain alone—self-interest, which has induced me to become the proprietor of a licensed house, and at the risk of subjecting ourselves to the most mercenary imputations, I must again express my greatest apprehension, whether any other motive in the long run will be adequate to secure sufficient accommodation and attention for private, or indeed public patients, afflicted with mental disease. Pure, disinterested philanthropy, we fear, could not be trusted where so much time, forbearance, and patience are required. Too few Howards have yet visited the world for the consummation of this delightful dream, and mental invalids must still be trusted to the guardianship of those with whom private gain is the chief motive. There is no concealing this most obvious truth, and it is idle romance to indulge in any other train of fanciful speculation.

To conclude this great *questio vexata*, I must reiterate most decidedly my candid opinion, grounded on some reflection and a little experience, that enlightened self-interest, guided by science, and spurred on by a moderate competition, will eventually accomplish a larger measure of interest and attention to be devoted to cases of insanity than can ever possibly result from purely eleemosynary means.

I feel that in arguing this point I tread upon very delicate ground, but as the great moralist Johnson has said, argument is argument after all, notwithstanding it be used by interested parties, and no fear of senseless reproach shall deter me from uttering my sentiments on so important a point. There is no question that public sympathy has been unfairly appealed to, that the matter has been only very superficially examined by declaiming writers,—for instance, such as those who figure in "Household Words," &c.; but these appeals have had more or less effect in begetting prejudice against private institutions, and what has alarmed me

more, have even influenced men of great learning and experience, I mean the Commissioners in Lunacy, for I imagine I already perceive in them a slight tendency to discourage private asylums. And whilst touching upon this topic I cannot withhold expressing my general approval of the conduct of Her Majesty's Commissioners in Lunacy. I consider the Commissioners—barring a little over fastidiousness on some points, and which has rather grown upon them of late—are impelled by a strong desire to do their duty to the public, and my own experience says that they faithfully execute this duty so far as the very difficult and delicate circumstances in which they are placed will admit of. I also consider the last Act of Parliament on the subject about as perfect as human laws in the present state of the world can be made. If the legislators should attempt to be over stringent, and refine too much, and the Commissioners in Lunacy wax more and more exacting, and not be careful to exercise a large amount of cautious discretion in their proceedings, I fear the surveillance of these institutions will become such an intolerable nuisance, that few upright, scientific, and honourable men will be found ready to undertake their superintendence. Candour and justice, however, I must repeat, compel me to speak of the Commissioners with respect, and although their visits are hasty and rapidly accomplished, yet their great experience and tact in knowing what they are about, permit few things to escape their notice; and in nothing, perhaps, is their penetration and discernment more conspicuous than in their perceiving and sifting out convalescent patients. Probably it would not be difficult to find fault with some parts of their system of inspection, but as my letter is already too long, I must refrain for the present. Perhaps at some future time I may feel inclined to resume the subject, as there are still many very important points left perfectly untouched; and, in the mean time, I beg to say, that I have full confidence in entrusting our interests and motives to the care and guardianship of the members of the medical profession, who constitute the ablest and most impartial tribunal on this subject of inquiry.

I remain, yours very obediently,

AN ADMIRER OF TRUTH.

ABSCESS OF THE CEREBELLUM, WITH CARIES OF THE PETROUS BONE.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—The readers of your *Journal* must, I am sure, in common with myself, have been much interested in the very important "Case of Abscess on the Cerebellum, with Caries of the Petrous Bone," which is so ably related by Dr. Budd, of Bristol, in a late number. The very significant but temporary improvement which a second and third time excited false hopes in the friends of the patient, and might easily have deluded a less observant practitioner than Dr. Budd, is not an unusual occurrence when matter is forming in the cerebellum; and it is in this critical stage of temporary

reaction, that I take leave to offer a few observations. The marked improvement in the case on the 17th and 19th of June, and on the 7th of July, especially on the two former occasions, may be fairly attributed to the active and most judicious treatment of the case; and the lesson taught by the fatal termination of the case, and the well-described *post-mortem* examination, is evidently this:—that we are not to conclude that we have placed our patient on safe ground, when we have successfully combatted the most alarming symptoms.

Several cases of this kind have fallen under my notice. In three of them the symptoms were so perfectly parallel with those of Dr. Budd's, that I cannot but conclude that mischief of a similar kind was going on. Not feeling satisfied with the temporary abatement of the symptoms, I ordered the treatment, which was essentially the same as in this case referred to, to be pushed still farther. After the use of leeches, mercury, and blistering, a more permanent drain was established by a seton inserted in the nape of the neck; and I can speak with the greatest confidence of the value of this simple expedient, in cases where there has been a discharge from the meatus, alternating with intense headache, and other marked symptoms of internal mischief. In such cases the effect of the seton appears most beneficial.

It appears to have a marked control over the cerebral symptoms, more particularly in those cases that have a *benumbed sensation over the side of the head and face*, which generally precedes the paralysis. In other cases, where there had been a chronic discharge from the meatus, suddenly subsiding with internal symptoms, the seton is also found most useful, not only in relieving the severity of the cephalic affection, but in restoring the discharge from the meatus.

I am, Sir, your obedient Servant,

WILLIAM HARVEY,

2, Soho Square.

ABSORPTION OF THE MAMMÆ OR TESTES UNDER THE USE OF IODINE

To the Editors of the Provincial Medical and Surgical Journal.

GENTLEMEN,—A perusal of the literary periodical called "Notes and Queries" has suggested to me that a page of the *Provincial Medical and Surgical Journal* might be very usefully devoted to queries and answers on professional subjects.

If this suggestion meets your approval, I send a query to begin with:—

Have any instances been observed and noted, by any readers of the *Journal*, of absorption of the mammæ or testes under the use of iodine? If any, what preparation was used, in what doses, and for how long continued?

I am, Gentlemen, yours obediently,

A. CRISP GALL.

Ripley, Dec. 1, 1851.

QUACKS AND THEIR ADVERTISEMENTS.

[We extract the following from *The Critic*, of January 1, 1852. It would be well for the public if other journals would follow so laudable an example.—
ED. P. J.]

To the Editor of The Critic, the London Literary Journal.

SIR,—From the enlightened views and excellent tone which pervade your paper, I feel confident that you will not be inattentive to a remonstrance which I now make against *The Critic* being rendered instrumental in fleecing your incautious readers by the luring advertisements of quacks. The admirable and comprehensive summary which you give, of all that is passing in the literary and scientific world, makes your paper an invaluable medium of family instruction; and it cannot be a matter of indifference to you that, from any oversight in the commercial department, your work should sometimes be made the medium of presenting to the public the cheating baits of impudent empirics. I know that you do not desire to give place in your columns to such announcements; for some time ago, when I stated that Holloway's advertisements were inconsistent with the character of a high-toned literary and scientific journal, you not only listened to my expostulation, but took such measures as prevented their being again inserted. I wish that cheating advertisements of pills, ointments, and nasty books were regarded by members of the medical profession, and by fathers of families, with the abhorrence which they deserve; but so long as some London, and many provincial newspapers, teeming with the worst and most indelicate matter of this kind, are allowed to lie on the drawing-room tables of our gentry, the conductors of these papers are certain not to refuse them a place. It is, therefore, because I believe *The Critic* to belong to a higher class of periodicals, that I now address you; and as illustrations are often better than abstract arguments, I subjoin for your information a brief statement.

The following advertisement appeared in *The Critic*:

"A speedy cure for Stone and Gravel will be sent to any person by enclosing thirteen stamps to Thomas Wilkinson, Land Agent, Gainsborough, Lincolnshire."

A patient of mine, who is an intelligent gentleman, and one of your subscribers, sent thirteen stamps to Thomas Wilkinson, and received the following reply:—

"Dear Sir,—Your 13 stys are reced beg to say Instead of a Dose of Egyptian Drops, I will send the recipe for 36 stamps more and full directions how to Mix and Take it. Drops will dissolve the Stone and bring it away in Sand Quiet easy speedy cure is certain your respy Thomas Wilkinson, Land Agent."

This reply so much incensed my patient, that he at once intimated to Mr. Wilkinson that he would publicly expose him if he did not give the "speedy cure" in an *available form*, whereupon, in reply, the following evasive epistle was received, which I may state has not induced the invalid to discontinue appropriate treatment.

"Dear Sir,—Yours is recd. recipe return'd. 1 oz Barbadoes Tar 1 oz Balsom Sulphur 1 oz Linseed oil 1 do. Spirits Turpentine. On receiving the stamps full

Directions will be returned. Yours respy Thomas Wilkinson, Land Agent."

I need hardly add, that the recipe is nonsense; and even were it a good prescription, the want of directions for its use would render it valueless to a patient. The offer of a cure therefore for thirteen stamps cannot arise from a delusion on his part as to the efficacy of his nostrum, and is simply a clever method of obtaining money—not certainly for value received.

I am, Sir, yours, &c.,

JOHN ROSE CORMACK, M.D.

Essex House, Putney, Dec. 23, 1851.

[We thank Dr. Cormack for his communication. Assuredly the advertisements of Mr. Wilkinson shall not again appear; and, as regards all advertisements vigilance as to their character shall be exerted.—ED. CRITIC.]

Medical Intelligence.

THE HUNTERIAN ORATION.

The Hunterian Oration will be delivered at the Royal College of Surgeons on the 14th of February. Mr. Luke, one of the Vice-Presidents of the Royal College, and Surgeon of the London Hospital, will be the orator on the occasion.

STATISTICS OF THE PROFESSION IN PRUSSIA.

A statistical account of the medical profession has just been published at Berlin. According to that document, there are at present 287 district physicians, 3,266 practitioners, 962 surgeons of the first class, and 973 of the second class. Sum total, 5,488. These figures being put by the side of the amount of population, which was at the last census 16,216,912 souls, will give one physician or surgeon for about 3,000 inhabitants. The number of veterinary surgeons is 828, and the apothecaries amount to 1,478.

KING'S COLLEGE HOSPITAL.

At the last meeting of the Committee of Management of this hospital a letter was read from Mr. W. H. C. Plowden, one of the Directors of the East India Company, announcing his intention of placing at the disposal of that body the appointment of an assistant-surgeon in the Company's service, to be conferred on one of the students of the hospital, who is to be selected for his professional merits and his correct and gentlemanlike conduct. Such a noble and judicious exercise of patronage reflects credit, not only on Mr. Plowden, but also on the Institution which he has thought worthy of his bounty. Were the disposers of the patronage of the East India Company to adopt a course like this more frequently, the result in a few years would be most favourable to the Service, and would exercise a beneficial influence on medical science in India by introducing into it a number of highly-

educated young men, selected for the appointments specially for their diligence, industry, and medical attainments.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 9th inst. :—Henry Ayliffe, South Australia; Sydney Alder, Wakefield, Yorkshire; William Thomas Bell, Great Grimsby, Lincolnshire; Leonard George Boor, St. George Street, East; William Henry Brodbent, Manchester; William Coyle Dobson, London; Andrew Sexton Gray, Dublin; Thomas William Harle, Bishopstortford, Herts; Edward Coyleton Liddon, Devon; Wm. Geo. Lloyd Ingram, Midhurst, Sussex; Bernard Rice, Stratford-on-Avon, Warwickshire; Edward H. Swete, Bristol; Aldborough L. Williams, St. Helier's, Jersey.

THE FELLOWSHIP.—The next classical and mathematical examination for the Fellowship of the College will take place during the first week in March. The next professional examination for the distinction will take place in April next.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, Jan. 1st, 1852 :—George Arthur Humble, Ludlow, Shropshire; Joseph Stead, Manchester.

OBITUARY.

On the 3rd instant, James W. Fullerton, Esq., aged 37, surgeon of the *Amazon*, Royal Mail steam-ship.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

Gentlemen will observe that the Annual Subscriptions become due on the First of January, those who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association, Worcester.

Members who wish to propose Associates are reminded, that as the subscription commenced on the first of January, it is the most convenient time to introduce new Associates.

It is also particularly requested that all post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

JAMES P. SHEPPARD, Secretary.

Worcester, January, 1852.

TO CORRESPONDENTS.

Communications have been received from E. B., Dr. Swayne, Dr. Barclay, Dr. Dickenson, Mr. Barrett, Mr. Reid, Dr. Cooper, A Member, Mr. Cocking.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

CLINICAL LECTURES ON THE PRACTICE OF PHYSIC,

DELIVERED IN THE
THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D., EDIN.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c.

LECTURE XII.

ON THE MORBID CONDITIONS OF THE LUNGS, ETC., CONTINUED.

GENTLEMEN,—The indications of treatment in all inflammatory affections of the lungs are, to relieve the circulation and respiration by local or general abstraction of blood, to establish counter-irritation, to break down the fibrinous condition (or crisis of the blood, as it used to be called,) by mercury, &c., to lessen the force of the circulation, and promote the expulsion or absorption of the foreign deposits. If the inflammation only arise as one of the complications of fever, it is, of course, to be treated distinctly as such; for neither general bleeding nor general depressants would be admissible in typhus: and, in any case, all the above agencies are to be regulated and modified according to the constitution of the individual patient and the degree and extent of the action. In a common mild bronchitis little more will be necessary than a simple expectorant, or balsamic astringent. The first is applicable to those cases of deficient excretion in which tenacious mucus is lodged in the bronchi, exciting a dry tickling cough, without expectoration. In such a case very minute doses of antimony, say the 1-16th of a grain, thrice a day, with ipecacuanha and hyoscyamus, will speedily induce a thinner secretion, which shall wash off the tenacious mucus, and terminate the complaint, if treated thus early. But if it has run on much further, either from time or from the laxity of the constitution, so that there is profuse expectoration of watery mucus, or of phlegm, or pus, then the astringent balsamics and mineral acids will best serve our purpose. In such cases, the essential oils of turpentine or juniper, or balsam of copaiba, with sulphuric acid, will quickly stop the discharges and allay irritation, if they arise only from bronchitis. In more chronic cases, where the tubes have become permanently engorged or thickened, such simple measures will not suffice, but the counter-irritation of a series of blisters, or vesicant ointment or oils, must be had recourse to, along with occasional small doses of mercury; and, if asthma is apt to accompany this condition, anti-spasmodics must be used, the best, in my experience, being the ætherated lobelia. In very acute and extensive attacks the treatment must be proportionately vigorous, yet keeping in view the stamina of the patient. Should he be excessively robust and plethoric, and be labouring under great dyspnoea and high febrile excitement, blood may be abstracted from the arm. You may, perhaps, observe

that I myself scarcely ever resort to general bleeding in any case whatever. This arises from the simple consideration that local inflammation is not the result of a positive overplus of blood in the body, but only of a loss of balance in the circulation, whereby there is more in one part than there ought to be. To re-establish the natural balance it is not essentially necessary that all the other parts should be drained before the diseased part is relieved; for such an indiscriminate practice would give rise, as in olden times, to protracted convalescence, and perhaps permanent injury to the constitution. It is only requisite that the local hyperæmia should be reduced by local abstraction of blood, and that such local abstraction should be repeated as often as a fresh influx should render it desirable. By this means you fully meet the emergency, without trenching much on the general vigour of the system; nay, if the abstraction be well apportioned to the degree of hyperæmia at its commencement there will be no loss of blood, properly speaking, at all; for all the local overplus has ceased to have the nutritive qualities of true blood, and has no other office to perform than to excite pain and irritation, and disorganise the part. Even in thin and weakly subjects, therefore, the direct removal of this useless, and more than useless, material, rather tends to augment the general energies than to distress them. Thus much I have thought it necessary to say against general and in favour of local bleeding. Yet there are instances of acute attacks of such vital organs as the brain, lungs, or heart, that no safety is to be anticipated, except by making a rapid impression on the whole system by means of drawing blood from a large venous orifice; and thus, though the measure is not often to be resorted to, it may yet afford the sole hope of recovery in such extreme cases as I have instanced. There are also cases of asthmatic bronchitis, with carry blood, which demand these large bleedings. Generally speaking, however, even in bad cases of bronchitis or asthma, local leeching or cupping will accomplish all our intentions in that respect; and being duly followed up by blisters, or other counter-irritants, with mercury and antimony, and lobelia, we shall find that the force of the inflammatory action will be sufficiently arrested to permit of the use of simple expectorants, as a conclusion of the curative plan. Such affections, however, will often be obstinate, and, from the amount of morbid exudation that is thrown out and changed into pus, may greatly reduce the bodily powers, and keep up a hectic fever. Under these circumstances, it is desirable to act well upon the bowels, and to constringe the capillaries of the bronchi by the balsamic and mineral astringents already spoken of. This was well exemplified in the case of Hugh Bartley, the tanner, whose muco-purulent expectoration was of such amount as would have given rise in former times to the suspicion of phthisis; yet this was reduced, under such remedies, almost from day to day, until none appeared at all, and the case ended in a complete restoration of health. Not so in the young woman, Emma Perkins, under fever. In her the inflammatory action seemed gradually to diminish from below upwards; but at

length it fixed upon the larynx, and she died rapidly from œdema glottidis.

In pneumonic inflammation our proceedings must be still more decided; and even in its most limited extent it is to be viewed with a serious eye, as we know not how soon it may extend over the whole organ. The danger, as already stated, will also be greatly magnified if any other portion of the lung be previously in a state of consolidation, either from tubercle or a former inflammation. In full subjects, repeated bleedings from the arm may be necessary, amounting to sixty ounces, perhaps, or upwards; but in almost all cases cupping or leeching will be advisable in the first instance, followed up immediately by blisters. Mercury will also be employed with advantage; but, beyond all doubt, antimony is to be viewed as the grand and almost specific agent for the subduction of this alarming disease. The little girl, Bates, only affords one example out of hundreds of the peculiar action of this remedy, which may, under such circumstances, be borne to an astonishing amount without exciting sickness, though I have never tried, nor found it necessary to try, the extraordinary doses of this medicine recorded in French practice. One quarter of a grain every hour or two, or half hour, will usually be found quite effectual; and the daily record kept of Bates' respirations, after taking these doses, illustrate to you its steady and beneficial operation. From 58 they came to 40, and so on to 30, and 20, and 18, until they were of the natural number (16) that might be expected in a girl of 12 years of age. There certainly are occasions when this line of treatment is inadmissible; as, for instance, in the case of Ann West. Here, the circulation was scarcely perceptible, the feet were cold, the tongue black, the respirations 42, and the amount of liquid effusion so great that we had the tracheal as well as the bronchial rattles large and universal; the face blue, and the body lean and anasarcaous. Besides all this, there had already been an extensive deposit of tubercle. Both of the house-surgeons anticipated her death every moment. On seeing her, I considered that there was no hope except from stimulation. Accordingly, she took aromatic spirit of ammonia and small quantities of hot brandy and water every hour or half-hour. Under these agents the heat of the legs returned, the tongue became cleaner, and the face less blue; the pulse reappeared, she was able to expectorate in some degree, and thus survived for a space of ten days,—viz., from October 18th to the 28th of the same month, when she died. The left lung, as reported after the autopsy, was found quite gone, except a pouch at the apex, and the right was inflamed, and choke-full of glairy mucus, blood, pus, tubercle, and other morbid exudations. The liver was large, and of nutmeg appearance. It had had an attack of inflammation immediately previous to this onset of pneumonia; and it was from the depleting measures resorted to under that prior ailment that we were deterred from resuming them under the last pulmonary attack. She was certainly, as a phthisical subject, making apparently good progress, until this hepatic affection came on, followed by pneumonia. Her face

was even becoming much fuller under the influence of the cod-liver oil when enlargement and pain of the liver was first discovered; and, after that was in some degree subdued, pneumonia next set in. I do not state it as any fair or legitimate deduction from the sequences of this case; but, from what has been elsewhere asserted, I am inclined to admit, as a matter of suspicion, that this may be one of those instances in which pneumonia is said to be traced to the use of the cod-liver oil. Certainly the lungs, when reduced in capacity, (here the left was entirely wanting,) and especially when the liver is also unfitted for its functions, may become oppressed by any undue amount of oleaginous materials in the blood; and such may have been the true history of this case, and of others adduced by the practitioners alluded to. But I am not disposed to admit that it is a frequent occurrence; and the experience of our hospital in phthisical cases, which has been pretty extensive, would certainly never warrant us in viewing such an event as any other than a rare occasional accident, granting even that it does take place, which is not thoroughly proved. Some analogy is endeavoured to be established between the assumption of oil by the mouth, and its injection into the veins; but it is quite obvious that there is no vital similarity between the injection into a vein of crude, oily globules, foreign to the frame, and the same oil globules subjected to the operation of the gastric juices, and absorbed and assimilated in the chyliferous ducts, &c., before being mixed with the cardiac and pulmonary blood. You will understand, therefore, that I neither admit nor deny the assertions of these gentlemen; but, considering that the investigation is an important one, I willingly give them the benefit of a case that seems to tell in their favour.

After the inflammation is so far subdued by the active agencies already alluded to, as known by the return of crepitation and easiness of breathing, simple expectorants will prove of great advantage in throwing off the accumulation of morbid matters in the chest, the debris, as it were, of the previous disorganizing process. These, as already stated, are to be selected according to the tenuity, or tenacity, or purulency of the expectoration; and, if there continue, as there sometimes does, an exudation of red globules from the relaxed capillaries, even after all inflammation has been overcome, as exemplified in Thomas Steele, then sulphuric acid may be used, or, what is far more efficacious, and perfectly safe, acetate of lead. Steele's affection was never thoroughly cured till this was used. If we have reason to believe that any degree of consolidation remains after the inflammation has left, a course of iodide of potassium, along with blisterings, may be required, as no expedient should be wanting by which we may restore so vital an organ as the lung to its natural conditions.

Besides these acute inflammations, there may occur a simple passive congestion of the lungs, leading to an insufficient oxygenation of the blood, with dyspnoea, asthma, and all the other necessary consequences of pulmonary engorgement. It is usually to be distinguished from the acute form of hyperæmia, by the less

disturbed state of the pulse; and, if it do not, proceed from a mere sluggishness of action in the vessels of the lungs themselves, it may ordinarily be connected with the existence of some obstruction at the left side of the heart. Thus, in the above case of Steele, who was a man of forty-four years of age, who had a severe attack of hooping cough, treated by my clinical clerk, Mr. Metcalfe, and who afterwards entered the hospital for the chronic sequelæ, consisting of teasing cough, shortness of breath, weakness, and profuse rust-coloured expectoration; we inferred that the whole vascular system of the lungs was in a state of engorgement and relaxation, so that the functions were not only impeded, but blood exuded through the capillaries. Local blood-letting and counter-irritation subdued this condition to a certain extent, but it never wholly disappeared till the acetate of lead was exhibited, the effects of which were very remarkable. Most of the other cases seemed to arise from concentric hypertrophy of the left side of the heart, as in those of William Peakman and Eliza Bond, characterised as they were by asthmatic dyspnoea, forcible action of the heart, and extended dulness; but yet a small pulse, dusky complexion, blue lips and nails, and a tendency to coldness in the extremities. In the case of Peakman, where this state of things had not been of such long-standing as to impair the flesh and strength, comparatively speedy benefit was obtained by regularly repeated cuppings over the chest, and even bleedings from the arm, accompanied with expectorants and antispasmodics; but as they are generally of old date, and have already reduced their victims to a state of meagreness and debility before the physician is consulted, he can seldom resort to more heroic measures than the administration of a soothing expectorant and occasional abstractions of small quantities of blood, whenever the engorgement seems to be of greater amount than usual; and even such little quantities are often difficult to be drawn, from the morbid thickness of the fluid. It is almost needless to observe, that all exercise, and everything else that may exalt the action of the heart, will prove injurious, and that a light nutritious diet, therefore, and a quiet tenor of life, will be absolutely indispensable. Unfortunately, however, this is a course which can seldom be carried out for a sufficient length of time among the masses of the working population, who, consequently, become victims to a succession of secondary and tertiary evils, and ultimately sink under dyspnoea, dropsy, and enlarged liver and kidneys, as well as hypertrophied heart, in one complication. This result was never better exemplified than in the person of Henry Foxhall in the detached wards, who having been a blacksmith, and accustomed from his industrious turn to wield a stupendous hammer for many consecutive hours, at length brought cardiac hypertrophy on himself, accompanied with regurgitation, &c., apparently from incrustated valves. This naturally induced pulmonary engorgement, with dyspnoea, and the whole chain-work of the central circulation becoming involved, he came to me, chiefly complaining of the next series of sufferings, namely enlarged liver, albuminous urine, and anasarcaous limbs, with ascites. He was periodically

cupped over the chest, which relieved his breathing, and he also took gentle diuretics, sudorifics, and drastic purgatives; but these effected no remarkable change during the month he was under treatment. Like all uninformed people, he looked upon the dropsy as his essential disease, and having heard, no doubt, of sundry cases of simple dropsy being simply overcome, he became, I suppose, impatient of the slow or rather no progress, and so left the hospital, perhaps to seek some more promising advice. So will such a man go from physician to physician, and from hospital to hospital. Although they may stave off the impending fatal issue, yet, because he is not cured, he continues to lose confidence in the faculty, and at length resigns himself to the mortal changes which are slowly yet surely going on within him, or consents to be more speedily dispatched by some such decided remedies as cuticular incision, or violent diuresis, at the hands of an empiric. So much for pulmonary congestion, its causes, and its remote effects.

In regard to the degenerations of the lung, they are of diverse character, and shall be more specially treated of when we come to consider the diseases of the blood, in conjunction with those of the ganglionic innervation. In the meantime, I may merely glance at the conditions of mollification, melanosis, gangrene, tubercle, and cancer.

SIMPLE MOLLIFICATION, apart from any previously inflammatory action, is usually found as the consequence of a long continued liquid state of the blood, combined with a tendency to dispersed tubercle. It is most apt, therefore, to be discovered after death from scurvy, or from delirium tremens, or typhus fever. In the patient, Edwin Neal, a tailor, who had led a very dissipated life both as to women and drink, and who had repeatedly been attacked with delirium tremens, while he had, also, the symptoms and appearances of the tuberculous habit, we found, after death from such form of disease, that the whole of both lungs was reduced to a friable and soft state, with almost no appearance of structure. The mass had no crimson aspect as from acute inflammation, but rather felt like softened spleen, and had a brown coffee ground colour, interspersed with whitish specks, like liquid tubercle. It seemed altogether as if there had been a chronic pneumonia of low vitality, which had thrown forth vitiated blood, and a tubercular infiltration, instead of plastic lymph, and that, ultimately, the whole structure had settled down into this kind of debris, under the dissolving influence of the extremely fluid blood. Such results can only be averted by the tonic regimen, and a careful attention to diet and exercise; for when they have once occurred, I see no means whatever for a restoration.

MELANOSIS is a very peculiar state of the lungs, frequently traceable to the direct inhalation of carbonaceous matter, as in coal-mines and the like; but also sometimes referable to a carbonaceous deposition from the blood. This event usually occurs amongst those who have taken an excess of carboniferous matter into the system in such a subtle shape as to render it likely to reach the lungs. Hence, no excess of bread or oil

will probably bring about such a result; because the particles being in a coarser form, are not liable to be absorbed in unnecessary quantity, but will rather pass off in defecation. But spirits, on the other hand, appear, *a priori*, very likely to have their ultimate elements so attenuated as to enter with ease into the circulation, even though not required, and, therefore, to be deposited as an incontrovertible overplus within that organ, which would otherwise have expelled it in a gaseous form. The lungs of almost all people, but especially those advanced in life, have something of this melanotic aspect. But it is the habitual hard spirit drinker who is so peculiarly liable to it; and it may be recollected that a vast deal of this morbid matter was found in the case I have just described, as well as in others of a similar kind, wherein the pulmonary tissue seemed as if it had been intermixed with small specks of soot in all its parts, but particularly at the summits. As to the treatment of such a condition, I apprehend that it must consist more in prevention than cure; though I have little doubt that if the baneful habits be abandoned in due time such excessive deposits as may already have occurred will be ultimately decomposed and dispersed.

GANGRENE has already been alluded to as one of the possible consequences of inflammation, when it has run so high, and has been followed by such a degree of depression, as to lead to the local death of the affected tissue. But the true idiopathic gangrene, of which I now speak as an original degeneration, seems to be preceded by no inflammatory action, but to be simply due to a depression of vascular action, similar to that which takes place in senile gangrene, whether from partial paralysis of the nervous system, or from osseous or fatty deposits, or from obliteration of the vessels, or general degeneration. The only difference seems to be that the one manifests itself at the extremities of the systemic circulation, while the other is exhibited at the extremities of the pulmonic. Both, as may be inferred, are highly intractable diseases, though that of the lung is certainly the most serious. If the whole capillary expansion is involved there can be, of course, but one result; yet it may happen that only a limited portion of the lung is thus deprived of nutrition, &c., and so, after softening and decay, it may be expectorated, while the exposed surface heals up. And there is not so much fear of hæmorrhage under such circumstances as might be naturally expected; for experience teaches us that in idiopathic gangrene the larger vessels are almost always so closed up with fibrin, to some distance from the softened tissue, that no discharge of blood can take place. In the case of Richard Thomas, to which I may again advert for illustration of this point, we find a man first attacked by paralysis of the lower extremities, followed next by gangrene of the toes and heel, while scarcely a pulse can be felt during the whole period of the ailment. As the tongue, under wine and ammonia, turned from black to red, so the gangrene stopped at the toes, which dropped off, while the stumps seemed to heal kindly enough. At this period, however, he catches erysipelas. Quantities of matter are found

burrowing under the integuments of the leg; and an incision being made for its escape, the tibia next begins to show some sign of caries. Without any advance towards a fresh healing process, the bone continues black, and the wound continues to discharge and form sinuses, until he gradually sinks and dies. Now, after death, the heart is found nowise different from other people's, except that it is a little pale, and, perhaps, slightly fatty. But then, all the rest of the body is found not only to present thick layers of fat, while the muscular fabric is atrophied, but it is infiltrated with a fluid oil. The fatty layer of the abdominal wall is found about three inches thick. On cutting through the wrists, thighs, and legs, in order to examine the state of the radial, femoral, popliteal, and tibial arteries, the subcuticular fat is again found in great abundance, while the pale juices that flow out are saturated with oily globules. All the arteries are found narrowed in calibre. In the affected leg the tibial artery has become a fibrous chord, shortly after its departure from the popliteal; and the muscular masses around have become so degenerate as to cut, not like red animal flesh, but like the bluish yellow flakes of a stale white fish. Such is gangrene, apart from any true inflammation.

This gangrenous condition of the lung is readily to be recognised by the intense and peculiar foetor of the breath and sputum; and the only hope of overcoming it, if it be limited only to a portion of the organ, consists in maintaining the vigour of the circulation, correcting the septic tendency, and assisting the expulsion of the deteriorated matter. The agents most likely to effect the first purpose are such diffusible stimulants as wine and ammonia, exhibited in such small and oft repeated doses as may keep up a constant and unflagging support; though too often, from the mistaken notions of the patient himself or his friends, the doses will sometimes be so raised as to induce a corresponding depression afterwards—a result the most pernicious that could occur in such a disease. The second object will best be gained by the administration of cinchona, coupled with the aëtic or muriatic acid, but, of course, at different times than the ammonia. As to the third object, of expelling the putrid matter, we must seek to do that by keeping every emunctory moderately open,—viz., the bowels, the kidneys, the skin, and the lungs; yet not so as to exhaust the strength. In such a case, I should content myself with the repetition of gentle effervescing aperients, with the exhibition of liberal allowances of yeast beer (as one of the best antiseptic diuretics), and with such a diaphoretic and antiseptic expectorant as the compound tincture of camphor. As I have had no case of the kind in this hospital by which to illustrate this local disease, I shall limit myself to these general remarks.

THE TUBERCULAR DEGENERATION opens up to us one of the most extensive, and important, and difficult questions in the whole range of physic; and it is no less interesting than it is extensive, and important, and difficult. But, viewing the tubercular and other degenerations as due to deeper causes than any mere local

affection of the lungs, I shall defer treating of it at any length, till I come to that part of our course in which we shall take a review of the diseases of the blood in connection with defect of ganglionic innervation. I shall only at present indicate my general view of this condition, leaving its particular pathology and treatment to be illustrated hereafter, by the citation of those numerous cases which we have seen within the walls of the hospital. The most ordinary and most serious manifestation of the diathesis is a deposit of tubercular matter within the tissue of the lungs, commencing commonly at the summits. This, I believe, in the vast majority of cases, to be preceded by some degree of weak chronic inflammation or hyperæmia, the deteriorated exudations of which, from the deficient vitality, become the nidus for tubercular infiltration. On referring to the case of the little girl Tilley, you find that no tubercle was discoverable in the lungs, but that it was found in the false tissues which had glued the peritoneal and pleural surfaces, &c., &c., to one another, in short, in every part of the body, where former inflammation had poured out plasma, such as it was. This I take, amongst other facts, as a strong confirmation of the above view. It is also to be remarked, that tubercle is chiefly found in the upper parts of the lungs, exactly where we would expect and know that irritation is most frequently excited by the inhalation of dust, &c., &c., giving rise to frequently recurring, though limited, bronchitis. It must also be admitted, however, that such simple hyperæmia, from accidental causes, would not be so likely to induce tubercular deposits, unless the blood were already in a deteriorated condition. Hence, in that diathesis, we find the blood more abundant in fibrin than usual, and less charged with the oleaginous and red globules and albumen, than it ought to be. This, again, we trace to a defective condition of the organs of assimilation, not merely as represented by the stomach, liver, bowels, &c., but by the whole range of the machinery of nutrition, as indicated by the feeble pulse, thin blood, and pale or transparent tissues of the entire frame. On finding this to exist, in spite of the best supplies of nutrient materials, and without any discoverable lesion in the visible organization, we must be led to conclude that such unhappy effects must be due to a weakly and irritable condition of the ganglionic innervation, upon which all such processes are known to depend, although we cannot demonstrate its mode of action. That they are owing alone to this defectiveness in the unconscious brute operations, and their governing nerve, and not to any impropriety in the cerebro-spinal system, is clearly demonstrated by the very frequent manifestation of a fine sensibility, and a clear, exalted intellect, accompanying this organic degeneration; and, in short, by the fact, that there does not necessarily occur, in this disease, any deficiency whatever of the voluntary, mental, or corporeal energies, excepting from the debility that is traceable to non-nutrition.

Accepting these views, as true, and omitting for the present all mention of minute symptoms and special remedies, you may readily enough infer what should be

the general principles of treatment under the whole circumstances. To begin at the foundation. We first seek to uphold or increase the energies of the ganglionic system, not by the exhibition of active and exciting stimulants, but by those more mild and permanent agents called tonics, such as quinine, iron, silver, &c., along with good regimen and kindly sedatives. Specially we seek to impart tone to the digestive organs by means of aromatic bitters, and other means of improving the appetite and chylicification. In order, moreover, to supply right materials to these organs, when so strengthened, it behoves us to select the lightest and most appropriate nutrients at our disposal; and, seeing that there is a special deficiency in the blood of the oily and red globule, along with albumen, we have specially to supply such deficiency by means of oil and carbonate of iron, and albuminous diet, sufficiently charged with the calcareous phosphate. This comprehends the whole of the general treatment, while local lesions will demand local remedies. Thus, even granting that the doctrine of hyperæmia being the prelude of tubercle were incorrect, still there can be no doubt that, as soon as tubercle is deposited, it commences to irritate as a foreign body, and to excite a greater or lesser amount of inflammation, and all its consequences around it—therefore it will be necessary to use expectorants, and to excite counter-irritation, by blisters or otherwise, in the neighbourhood of the affected part. When the capillary relaxation leads to exhausting sweats, such astringents as sulphuric acid or lead may be required; and, if local inflammation go very far, it may even be necessary, though the patient be exceedingly weak, to abstract some blood. But, while such bye-treatment must be varied according to varying symptoms, and circumstances, and stages of the disease, the grand basis of curation must still remain essentially the same, and consist, as I have already said, in a restoration of the ganglionic nervous energy, and a supply to it of such materials as are fitted for the purposes of nutrition under all the circumstances of the individual case. You have had ample and frequent opportunities in the Queen's Hospital of estimating certain beneficial results from this line of practice, but I shall abstain from further comment until, on a future occasion, I shall refer to the special cases, and enter at large upon the minutæ of the question. Meanwhile I merely refer you to the records in the ward journals, bearing in mind that we have drawn no line as to the admissibility of patients, nor made any selection, with a view to better success, but have freely opened the door to all and sundry, whether in the incipient or the very last stage of this melancholy and fatal malady.

CANCER, in its different forms, I place under the same category as tubercle, so far as it is a disease of the blood, and of the ganglionic innervation. Like tubercle, it also seems prone to settle in such parts as have been previously exposed to the irruption of deteriorated exudations—as where the tissues have been already irritated, altered, and injured by long continued pressure, or repeated bruises or blows. The lungs are not a very likely place for such accidents; nevertheless, cancerous

tumours are occasionally seated within this tissue, giving rise to cough, with dulness on percussion, if the mass be large enough, or so situated as to be thus tested, and exciting, sometimes, a piercing and intense pain; but, it may be, no pain at all. Its peculiar nature, if discovered to exist, must be inferred from the general aspect and condition of the patient, and his family history; but, as little can be suggested for its alleviation, beyond the free exhibition of such sedatives as opium, aconite, hemlock, and the like, I shall enter upon no further clinical consideration of it in this local form.

SOME REMARKS UPON THE

IDENTITY OF WARTY ULCERATION OF CICATRIX WITH EPITHELIAL CANCER, ILLUSTRATED BY CASES.

By JAMES REID, Esq.,

SURGEON TO THE KENT AND CANTERBURY HOSPITAL.

Read before the East Kent and Canterbury Medical Society, Jan. 2, 1852.

THE disease, of which I now place before the Society a specimen, has been regarded and described as one almost peculiar to cicatrices; but I think it will be seen there is scarcely sufficient reason to consider it a special and distinct disease, but rather to associate it with one that is well known and is not of very unfrequent occurrence. When the case occurred, with which this specimen is connected, I was not aware that the disease had been described as peculiar to cicatrices, and from a due consideration of all the circumstances relating to it, I considered the nature of the affection was the same as that of cancer of the lip or of chimney-sweep's cancer. The appearance of the fore-arm forcibly reminded me of a preparation I had seen in St. Bartholomew's Hospital Museum, in which cancerous ulceration of the integument of the wrist and fore-arm had occurred to a gardener, and was supposed to have originated from the contact of soot used in his occupation.* From what I have since learnt and read upon the subject, I am still induced to retain the same opinion; for I have been unable to discern any real difference between the two affections. In order, however, that the merits of the question may be clearly placed before the Society, and as, moreover, from its rather unfrequent occurrence, the present form of the affection may not be familiar to all the members, I will give a brief sketch of its leading features as described by authors. The description is principally derived from an excellent paper on the subject by Mr. R. W. Smith, in the *Dublin Journal of Medical Science* for 1850.

The same disease appears to have been described under the name of "Warty Ulcer," by M. Marjolin;† "Warty Tumours of Cicatrices," by Mr. Cæsar Hawkins;‡ and as "Warty Ulceration of Cicatrices,"

by Mr. Smith. Dr. A. Jacob incidentally alludes to it in a paper "On an Ulcer of Peculiar Form,"* as the ulcer with cauliflower-like fungous growth, which occasionally attacks old cicatrices. With the exception of this simple reference, the earliest notice of the disease published in this country seems to be that of Mr. Hawkins, in which some of the peculiarities are clearly told and illustrated.

The tissue of cicatrices seems peculiarly liable to the development of this disease, though it is certainly not confined to such texture; for Marjolin does not, it appears, describe the disease in connexion with cicatrices. The nature of the previous injury does not influence the subsequent morbid changes. The disease generally forms when the cicatrix has existed several years; its progress is slow, but unceasing and destructive. Sometimes a cicatrix ulcerates and heals repeatedly before the ulcer assumes its peculiar characters.

In a list of twenty cases, collected by Mr. Smith, the longest period after the original lesion at which the disease appeared is sixty-one years; the shortest, five years. In twelve instances, the injury causing the scar was a cut or a laceration of the integuments, and in eight cases, a burn or a scald.

The affection appears to exhibit two principal forms:—The *first* characterised by the development of one or more warty tumours, which increase and spread by the addition of similar growths formed in the neighbourhood. This form was first described by Mr. Hawkins, and he admits that it may be cancerous or malignant in the lowest degree. The *second* presenting an ulceration having either a coarsely-granulated, or fibrous aspect, and spreading by the development of a new structure in surrounding integument; this is particularly described by Mr. Smith, and he assigns to it a low degree of malignancy.

The following seem to be the principal characters of the affection:—There appears in some part of a cicatrix a wart, or a small hard tumour, which either resembles a wart, or has a smoother surface. It at once undergoes certain changes, or remains inactive for a variable period. When the tumour increases, fresh growths spring up around, and coalesce with it, creating sometimes in this manner an elevated mass, of considerable size; the surface becomes moist, and partly ulcerated, yielding a thin offensive discharge; it is often very vascular, and bleeds when touched. In the progress of the disease several changes are noticed in the tumour; it may either become more consolidated, so as to lose, in some measure, its warty appearance, and resemble a fungous growth, (warty growths, however, being generally noticed near it, and its fibrous or striated structure being generally readily discovered by the use of a probe, or upon making a section of it); or it may degenerate by ulceration or sloughing to a greater or less extent, so as sometimes to leave a deep excavated ulcer; the thickened, warty, or peculiar state of the surrounding skin remaining, and the disease extending by the same process of contamination of adjacent parts.

* Descript. Cat., Museum, St. Bartholomew's Hosp. Series, xii., No. 6.

* Dublin Hospital Reports, Vol. 4, 1827.

In other examples, ulcerated spots present themselves on the cicatrix, and gradually coalesce; the surface of the ulcer is then either covered with closely-arranged fibres, of a whitish yellow colour, having a dense, but at the same time brittle texture, and rising above the level of the integuments; or it is formed of coarse, firm, round granulations, resembling the elevations of a cancerous ulcer. Upon a close examination, these granulations are found to have a fibrous texture, the intervals between them are well marked fissures, to the bottom of which a common probe can be readily passed. The progress of the ulcer is sure, and slowly advances in spite of remedies. It enlarges by an alteration of the surrounding tissue. The integument becomes raised, thickened, and fissured or warty; and then softens or ulcerates. After it has continued some time, although commonly confined to the skin, and frequently limited to the extent of the cicatrix, it spreads in depth by involving subjacent tissue; and if the disease is situated over a superficial bone, invades the periosteum, and even the bone itself, so that a fracture may result from the destruction. Mr. Smith cites instances of this. A sloughing process not unfrequently attacks and destroys the entire surface; the surface clears, and again assumes its special aspect. This does not appear to occur so often in the fibrous variety of the ulcer. The pain is at first slight, but gradually becomes more severe, and constant. The discharge is thin, semi-purulent, and frequently very offensive. In the more advanced stages of the disease hectic fever sometimes appears. The absorbent glands connected with the part are not generally affected, though they are frequently sympathetically enlarged; however, in two instances described by Mr. Smith, they exhibited the appearances which mark cancerous disease. General or local treatment of the ordinary kind has no effect upon the disease; its progress is inevitable, unless the diseased part is completely removed, when it rarely appears again. It has, however, been known to return in a distant part, and also to become developed in other parts of the system.

In the foregoing description, the analogy of this disease with that form of cancer designated epithelial, cannot have failed to occur to the members present; indeed so similar do the two affections appear, that I think there is no reason why they should not be included in the same category, and considered as identical. The mode in which the disease commences, the history of its progress, the manner in which it invades and spreads in subjacent and surrounding texture, affects the lymphatic glands, and penetrates bone, correspond entirely with what is observed in cutaneous cancer. The various forms agree; the warty tumour, the warty ulcer, and the granulating ulcer, with hard, elevated, everted, and sinuous margin, are found in each affection; the very character of the pain and of the discharge is alike in both. And, further, the reasons that have been assigned for considering it cancerous disease, possessing a low degree of malignancy, are the same as those upon which epithelial cancer is admitted into the order of malignant disease,—namely, its capability of converting neigh-

bouring tissue into a similarly new structure, though its progress in doing so is slow; its power of contaminating the lymphatic glands, while the period it exists without affecting the system is long; its return after complete removal,—this occurrence, however, being rare.

It will, therefore, be better to regard this disease, which has been considered as almost peculiar to cicatrices, as *epithelial cancer of cicatrix*. Why the tissue of cicatrix is liable to this form of cancer may probably be part of the same question which involves the explanation of the more frequent appearance of the same disease in the scrotum, the labia pudendi, the lip, and integuments of the face, than elsewhere.

The several forms of the malady are probably differences depending upon the greater or less proportion and development of some particular natural tissue with the malignant elements of the disease, and a diminished or increased degree of activity in the subsequent changes of the new structure. At the same time the original type preserves its peculiarities, to a certain extent, throughout the future progress of the disease, and rarely shows a tendency to pass into another; the vascularity, or some other special condition of a part, having, however, some modifying influence. Thus, the ulcer, originally fibrous, as distinguished from the granular form, may derive its peculiarity from the greater development of some component tissue of the skin, and retain this condition not only whilst confined to the integument, but also when it has penetrated bone. An instance is figured by Mr. Smith in which an excavated ulcer of bone thus originating is represented with closely-packed fibres arising from and covering its surface. This explanation of the different forms of the disease is somewhat conjectural, and requires the due consideration of more extended observation to confirm it; still there are many points connected with this affection, and epithelial cancer generally, which justify it.

The following instances of this disease have fallen under my observation:—

E. A., aged 33, was admitted into the hospital in August, 1849. She was a tall woman of spare habit, and had been burnt during her childhood on the right arm and side of the face and neck. The angle of the mouth was considerably depressed by the contraction of the cicatrix of the neck. The forearm was flexed upon the upper arm, and fixed at a very acute angle by a strong web of cicatrix which extended between them as high as the middle of the upper arm. The hand was prone and flexed; she could move the fore finger, and had been able, with some cleverness, to use her needle.

Ten years previous to her admission she had noticed a wart on the scar of the forearm, which gradually increased, and became ulcerated, yielding a thin discharge. On her admission, the whole surface of the forearm, from the elbow to the wrist, was covered with warty growths, closely set together, being separated by deep fissures and cracks, from the bottom of which issued a very offensive and thin ichorous discharge.

Some of these warts were vascular, and were covered with secretion, whilst others had a grey colour, and presented a more loosely fibrous texture; some few of these latter were partly detached, apparently possessing little or no vitality. The patient said that, occasionally during the progress of the disease, masses of warty growths would become loose and fall off. The surface bled occasionally when the dressings were removed. The patient suffered constant severe pain; she dreaded to have the arm uncovered, and begged to be relieved of the burden. The fœtor of the discharge was scarcely corrected by chloride of lime.

Considering the extent and seeming incurability of the ulcer, the sufferings of the patient, and the crippled state of the limb, amputation appeared to me the only resource, and in this opinion my colleagues agreed. The limb was removed by double flap operation in the upper-third of the arm, so as to avoid including in the stump any portion of the cicatrix. The wound healed by the first intention, excepting at the point where the ligatures passed out; one ligature remained a long time, and delayed her dismissal from the hospital.

The disease had not penetrated deeper than the integument of the forearm; there was, however, one point where it was doubtful if the subjacent tissue was not beginning to be affected.

A. C., aged 44, the mother of four children, a large leuco-phlegmatic person, was admitted into the hospital December 13th, 1850.* When a child she had been burnt on the posterior part of both lower extremities, but more especially on the left, in which there was a cicatrix extending from the hip to the ham, producing slight contraction of the knee-joint. About eight years since an ulcer had formed in the middle of the scar of the left thigh, which had slowly healed under treatment. Five years ago it reappeared, and has continued gradually increasing. When she was admitted there was a large oval ulcer on the posterior surface of the left thigh, yielding a thin offensive discharge. Its surface was coarsely granulated; the granular elevations were florid, and the largest of them were about the size of a large pea, and had a rough appearance resembling a flattened wart. These elevations were separated by shallow grooves, which admitted the end of a probe. The edge of the sore was sinuous, raised, and everted, and the adjoining texture in some places thickened and indurated to a slight extent. Before the patient entered the hospital I had seen the ulcer at intervals, at which periods it had presented the same aspect, excepting on one occasion, when it was less granular, and had rather a glazed appearance. On another occasion a slight attack of erysipelas had taken place in the healthy skin about the hip. The pain was constant, but varied in intensity, being generally proportioned to the more active or quiescent condition of the ulcer. During her residence in the hospital the disease slowly advanced in

the following manner:—A portion of the margin of the ulcer became more extensively indurated, thickened, and raised; increased pain was felt in the part, which slowly ulcerated, the destruction being co-extensive with the previously altered texture. The surface of this fresh ulceration had a foul greyish aspect, which seemed to be due to the deposit in the diseased portion of the cicatrix. The ulcer then remained in a quiet state for an uncertain period, when another portion of the circumference, either adjacent to or remote from the part previously diseased, became similarly affected, and underwent the same changes. During the period she was under observation the ulcer extended in this manner in a direction toward the knee and the outer side of the thigh. Two or three times the whole surface, which had generally a florid appearance, presented a foul grey surface, the general health being at the same time affected; in the course of a day or two this surface would clear off, and the sore regain its former appearance.

Treatment had no effect upon the progress of the disease. The various applications made to the ulcer afforded some relief to the patient; more, however, apparently, from a mental influence than from any direct effect upon the disease. Opium afforded much comfort. Donovan's solution was given. The surface was too extensive to be removed by caustic or the knife. She left the hospital in March, 1851, and I subsequently lost sight of her, as she soon afterwards went to America with her family.

The next case occurred in the practice of my friend Mr. Sicard, to whose kindness I am indebted for an opportunity of seeing the patient, and for being enabled to add the particulars.

E. R., aged 72, received a severe burn, fifty-two years since, by which the left arm became crippled. The fingers and the thumb were so much injured that they mortified, and were removed. The surface of the burn slowly healed, but during the next twenty years repeated exfoliation of bone from the ulna took place. On these occasions, inflammation attacked the fore-arm, and extended even to the upper-arm; a portion of the covering of the arm became black, and separated, leaving an ulcer, from which either several small scales of bone, or a larger portion, were discharged. The ulcer then healed, and remained so until more bone was about to be discharged, and, in consequence, fresh inflammation was set up. At last, no more exfoliations took place, and then the cicatrix remained sound for twenty-nine years. About three years since, an ulcer formed in the cicatrix on the outer side of the arm, away from the situation of the former ulceration; this became incrustated, and by constant addition to the base of the crust, a conical horny growth was formed, which after a time fell off, leaving a healed surface beneath. The part speedily re-ulcerated, and the same process was repeated. During one year and a half this occurred three times, and then the ulcer became permanent. The largest of these masses, which is preserved in the hospital museum, measures two inches,

* This case had only been a short time in the hospital, and the following one was only incidentally mentioned when this communication was read to the Society. I have, therefore, given a fuller account of them than was made at that time.

by one and a half across the base, and is one inch high. The two last crusts formed very quickly. The pain was considerable during the three years, but increased very much during the last twelve months, when the progress of the ulcer was more active; the discharge, which was very offensive, increased, and the general health was affected.

When I saw the patient in August, 1851, there was a large ulcer occupying the front and outer part of the fore-arm, and extending from the bend of the arm to within an inch and a half of the wrist. The whole surface was very coarsely granulated, and in some parts had more the appearance of fungous growths; some of the masses were as large as a small arbutus-berry, and, owing to the roughness of their surface, had a very similar appearance. To the surface of the most prominent part of some of these, a thin, hard, dark scale was attached, and by the aggregation of several of these scales the ulcer at that part was covered by a corresponding thin crust. Similar incrustations had separated with the removal of the dressings. The edge of the ulcer was raised, thickened, and everted. The surface bled very freely when disturbed, and the discharge from it was extremely offensive. The patient was very much enfeebled, and lay in a semi-conscious state. She died exhausted September 2nd, 1851. The question of removal of the limb had been put to the patient twelve months previously by Mr. Sicard, but she had refused to consent to it; she had lately requested it, but the low condition she was in prevented its being accomplished.

These three cases illustrate some of the varieties of this affection. The formation of incrustations in the last case, though to a greater extent, is analogous to what is observed in the formation of scabs in some instances of epithelial cancer of the lips and face. The tendency of the formation of scales on the surface of the granulations, which existed to the last, is a point pathologically interesting, for I suspect that they were an epithelial formation, and, if so, they would afford an illustration of the continuance of an early and peculiar character of the ulcer, which might have been expected to disappear in the more active progress of the disease; a microscopical examination would, however, be required to determine this satisfactorily.

It is a matter of confessed importance in endeavouring to attain a correct knowledge of disease that, at the same time we are careful not to associate together disorders in their nature essentially different, we should guard against unnecessary distinctions, grounded on differences in the degree of development, or a few slight variations of external form. It is with the view of avoiding a distinction of this latter kind, which was apparently inferred, and which does not seem really to exist, that I have offered the foregoing remarks, and would suggest that the forms of disease before mentioned, which have been considered peculiar to cicatrix, should be regarded as epithelial cancer of that tissue; and thus a step, in simplifying our knowledge of disease, and as a consequence, in directing our remedial measures, will be gained.

Since the preceding was communicated, I have met with several published cases, which appear to me to be examples of the same disease, though they have not been distinctly noticed as such. They are nearly all instances of the disease invading bone, the malady having originated in a cicatrix which had followed an injury, and which had remained sound for some period. The mode of origin, the warty growth, and peculiar aspect of the ulcer, its unceasing though slow destructiveness, its manner of spreading, and the success of complete removal, as well as some other general points of resemblance, led me to think that they belonged to the same disease.

I will simply add the references to these cases, observing that the one related by Mr. Stanley, at page 366 of his work, is particularly interesting from the fact, that Mr. Paget, by a microscopical examination of the growth, discovered the existence of scales resembling the epithelial scales found in carcinoma of the skin, thus affording an additional confirmation of the identity of the two diseases.

In conclusion, I will refer to a lecture by Mr. Humphry, "On Epithelial Cancer," recently published in the *Provincial Journal*, (No. xviii., 1851, p. 477), in which he has given an excellent and clear description of this form of cancer, and alluded to the analogy between it and this warty disease of cicatrix.

CASE OF

RETENTION OF BILE AND DISTENDED GALL-BLADDER.

By W. BUDD, M. D.,

PHYSICIAN TO THE BRISTOL INFIRMARY.

Read at the Quarterly Meeting of the Bath and Bristol Branch, Dec. 17, 1851.

THE following case, as being at once rare and involving a nice point of practice, may be considered worthy of being placed on record:—

John Morgan, aged 35, a man of spare habit, and by trade a butcher, was brought to the Bristol Royal Infirmary, on the 22nd of September, 1851, in a state of imminent danger. He had already been ill three weeks, and severe pain and urgent vomiting, from which, during the greater part of that time, he had little or no respite, had at length reduced him to a condition of extreme collapse. To judge from his looks, one would

* Page 10, Nos. 29 and 30.—Page 18, Nos. 42, 42a.—Page 29, Nos. 124, 125, 126, 127.—Page 448, No. 40.—Page 453, No. 54.

have said he was a man dying from some internal rupture. His features were sunken, his surface was growing cold, and his pulse could scarcely be felt. An enormous swelling, which was pointed out as the seat of the pain, and was the apparent cause of the other symptoms, occupied the whole upper half of the belly. Its lower margin evidently formed by the edge of an enlarged liver, could be readily traced, extending across the belly from one flank to the other. Just above and to the right of the navel, over a space as large as the palm of the hand or more, the swelling was much more prominent than elsewhere. Bulging abruptly out at this point from the surface of the general enlargement, it had just the look of a large abscess, which had reached the stage of "pointing." Over the same place fluctuation could be distinctly felt, and from its marked and superficial character, it was plain that the walls of the sac, whatever the sac might be, were very thin. The extreme tenderness of the part, however, prevented the examination that would have been necessary to trace its exact outline.

The history which the patient gave of this formidable state of things was brief and simple. Twenty-two days before admission, being at the time in his usual health, he supped plentifully on oysters, and got drunk on strong beer. At day break, on the following morning, he was seized with severe pain in the belly, followed by urgent vomiting. The quantity of fluid thrown up was very large, and exceeded much, he thought, what was taken in the shape of drink. For three days the bowels could not be made to act, and the case altogether appeared to have the character of ileus or intestinal obstruction, and, indeed, was so treated. At length, after taking much drastic medicine, and having repeated enemata, he was freely purged; and from this time the bowels remained loose, acting generally several times in the twenty-four hours. The vomiting did not the less continue; so that from the day of attack to that of admission—from the 2nd of Sept., that is, to the 23rd—little or nothing had been retained on the stomach.

The swelling and hardness in the upper part of the belly first attracted his attention about a fortnight before he was brought to the hospital, and had continued to increase from that time.

There were two other points of much interest in the case, as to which the testimony of the patient was very clear and precise. The first was, that there had never been the slightest shade of jaundice; and the second, that the matters ejected from the stomach were often green, and possessed the common characters of bile. The colour of the stools he had not particularly noticed. He had never on any former occasion suffered from gall stones, jaundice, or other palpable hepatic disorder; nor had he ever received a blow or other injury in the neighbourhood of the liver.

As to his general history, he further confessed that he had drank to great excess for many years; but that he could not discover that his health had, as yet, suffered in consequence. The more accurate results of clinical inquiry showed, however, that he had not escaped the penalties which attach to these fatal habits.

Taking all these points into consideration, the question now was,—What was to be done in the present emergency? As all the suffering appeared to be connected with the abdominal swelling, and as many circumstances pointed clearly to the distension of the sac, as its chief cause, the opening of this sac by puncture seemed to offer the most obvious means of relief. The great urgency of the case, the thinness of the sac itself, and the great tenderness of the parts around it, all seemed to invite to the operation. On the other hand, before taking so hazardous a step, it was, at least, necessary to have clear views as to the nature and seat of the tumour. But, unfortunately, these were not easy to obtain.

Many who saw the patient were of opinion that it was an abscess; but there were strong objections to such a view. In the first place, as far as could be ascertained, none of the common causes of abscess of the liver had been in operation; there had been no blow or other injury; and there was no reason to suspect present or former ulceration in any part of the intestinal tract. The positive evidence was still more opposed to this notion. There could be no reasonable doubt, in fact, that the illness, whatever its nature, was set up by the debauch of the 1st of September. Now, suppuration may possibly happen after an excess of this kind; but it is certainly not among the common consequences of a drinking bout. Inflammation thus excited in a hydatid cyst already existing is the only case that occurs to the mind in which such a result might ensue with any degree of probability: and even such a case as this is, as far as I know, entirely hypothetical. The only remaining alternative seemed to be, that the enlargement was caused by retention of bile, through some obstruction of the common gall duct; and that the sac was a distended gall bladder. And yet to this again there appeared to be—as, in the absence of all prior personal experience of such a case, I then considered—these two very great objections:—First, that there had been no jaundice; and second, that the matters rejected by vomiting were often green, and possessed the other characteristics of bile. There was every reason to believe the man's testimony as to this last point; for, according to the nurse's report, the matters vomited soon after admission were distinctly green and bilious.

Amid this perplexity I resolved not to meddle with the tumour, but simply to apply a large poultice to the belly, and to endeavour by appropriate means to allay pain and stay vomiting. With this view, and proceeding on the notion that an excessive development of acid in the *primæ viæ* might be an important element in the case, I ordered ten minims of Liquor Potassæ, and three of Liquor Opii Sedativus, to be taken every three hours. A single large opiate had been already administered. The event proved in a signal way the soundness of the motives which had led to the adoption of an expectant plan. The vomiting ceased after the first dose of medicine until ten at night, when he threw up a large pewter full of what the nurse described as green bile, but which, unfortunately, was not kept for exami-

nation. This crisis was followed by a sense of very great relief, with an almost total cessation of pain; and from that time the sickness never returned.

On the following day all pain had ceased; the abdominal tumour had entirely disappeared; and the liver had retreated nearly within its natural limits. Some slight tenderness in the epigastric region was all that remained of the truly formidable state of things that existed there the day before. The countenance was free from anxiety; the surface had recovered its natural warmth; and the pulse had fallen from 120 to 80. Hunger was now the chief complaint. The starved body was no sooner released from pain than it asserted, in its own emphatic way, its demand for the material needed to restore its natural proportions.

An alkaline mixture, containing equal parts of carbonate of magnesia and bicarbonate of soda, was now prescribed, with ten grains of compound extract of colocynth at night. The bowels did not move until the following day, after an enema. Some large and quite clay-coloured lumps were first voided, followed by more liquid matters, evidently tinged with bile. The evacuation was not examined so minutely, perhaps, as it should have been; but nothing like gall-stone was seen in it.

The remaining part of this singular history is soon told. From the first moment of relief the patient continued to mend, with scarcely an interruption. On the 4th of October he was strong enough to get up, and was, in all respects, convalescent. On the 29th of the same month he left the hospital, having gained six pounds in weight during the last fortnight of his stay. Two circumstances were, however, noted, a knowledge of which is important to the pathology of the case. The whole time the patient remained under treatment the stools were of a pale drab colour. They were not devoid of bile, but were only scantily tinged with it.

The other circumstance alluded to referred to the state of the kidneys. For the first four or five days the urine was distinctly albuminous. It was also *very acid*, and on being allowed to stand, threw down an abundant precipitate, which by examination with the microscope was ascertained to be almost wholly composed of lithic acid in large crystals. It contained, besides, some well-marked casts of the uriniferous tubes; and, as the specific gravity was never lower than 10.25°, the presence of albumen was supposed to depend on the existence of, perhaps, recent nephritis. This supposition was entirely confirmed by the sequel. On the 3rd of October the albumen had disappeared, and could never be detected again in subsequent examinations.

Many important reflections occur to the mind in dwelling on this remarkable case. In the first place, the obscurity which at first hung over its nature, was, in regard to the immediate source of danger at least, entirely removed by the event; for, it is scarcely necessary to remark, that after the crisis which occurred on the night of admission, there could no longer be any doubt, notwithstanding the absence of jaundice, and the frequent presence of bile in the *ejecta*, that the abdominal enlargement was caused by retention of

bile, through some obstruction in the course of the common gall-duct; and that the sac was, after all, a distended gall-bladder. One of the important points of the case consists, in fact, in showing that the concurrence of the circumstances here specified constitutes no bar to such a conclusion. It may be further added, that a little consideration suffices to show that the anomaly they seem to offer is more apparent than real. For, it is not too much to say, that this anomaly is at once explained by reference to the exactly analogous circumstances which are often observed in the case of retention of urine. In the one case, as in the other, the gland continues to separate from the blood the elements of secretion, so that the system is kept free from taint. In the one case, as in the other, these elements are cast out into the natural receptacle, which provides, by its gradual distension, for the gradually increasing accumulation. In both, again, the gland, as well as the bladder, yields to the distending power, and makes room, in its own way, for the fluid which the bladder has no longer space to hold. The parallel does not even terminate here, but extends to the mode in which that partial relief is obtained, by which alone, in many cases, rupture is averted; for there can be no reasonable doubt, that the bile which occasionally appeared in the matters vomited, in the case of John Morgan, had escaped from the gall-bladder by the same mechanism as that by which small instalments of urine distil from the over-distended urinary bladder in cases of retention there. The outward discharge of this bile, as proving communication between the biliary passages and the intestinal to be still extant, although obstructed, was, I need scarcely add, a fact of the first importance in regard to treatment. Very probably, too, it alone rendered the continuance of life possible for so long a period under such circumstances; for, failing the relief thus afforded, it is but too probable that the gall-bladder, tense as it was in spite of such relief, would have given way under the constantly-increasing distension.

In the absence of direct evidence the nature of the obstruction itself must of course remain a matter of conjecture. Judging from the circumstances amid which it arose, on the one hand, and the persistence of a partial communication on the other, the probabilities are, that it was caused by inflammation and swelling of the lining membrane of the duodenal and of the common gall-duct, propagated upwards from the gut. Microscopic examination of the stools might, perhaps, have thrown some light on this question, but want of time and other circumstances prevented my having recourse to it.

The great length of time the obstruction lasted tells much against the notion that spasm was much, though it might have been partly, concerned in it. Many of the circumstances of the case, however, among which I may mention the characters of the urine, coupled with what we know of the pathology of this class of affections, renders it not improbable that the irritant action of an excess of acid in the upper part of the *primæ viæ* might have played an important part in the phenomena. The continued deficiency of bile in the stools, after the

obstruction had given way, would admit of various interpretations. It might possibly have been owing to an early stage of cirrhosis, brought on by the drinking habits in which the patient had so long indulged, although this is improbable; or the secreting power of the liver might have been more or less impaired, as that of the kidney is often known to be under the like conditions, by the prolonged and severe pressure to which the secreting element had so long been subjected; or, lastly, some amount of obstacle might still have existed to the free flow of bile into the intestine.

Finally, it would be an omission to take leave of this case without remarking what a strong motive it furnishes, not less in the unexpected deliverance from so desperate a state by the common resources of nature, than in the probably fatal risk averted by abstaining from surgical interference, for extreme reserve, as well as caution, in attempts to relieve fluctuating tumours connected with the liver, by simple puncture with the knife or trocar. Altogether to proscribe such attempts would be, no doubt, to go too far.

In the 27th volume of the *Medico-Chirurgical Transactions* a case is recorded by Mr. Barlow, in which the operation of tapping a gall-bladder, distended by retention of bile, was not only followed by no ill result, but was, most probably, the means of saving life. Many circumstances, and among them some connected with its own history, concur to show, however, that it would not be safe to make the course followed in that particular case a rule of practice. For this one case of success many could be related in which the operation was the actual cause of death, and where the introduction of the trocar sealed the fate of the patient. It is a matter of experience, in fact, that in the majority of such cases the gall-bladder is non-adherent; and thus it happens, that (by the common mode of proceeding) the immediate effect of the puncture is to cause the pent-up bile to escape into the peritoneum, and thus to hasten on that very catastrophe which it is the great object of art to avert. But, notwithstanding all these difficulties and objections, it must still be confessed, that this mode of relief *will* occur to the mind as a possible means of saving life where death might otherwise be inevitable; and thus, in spite of former mishaps, on the one hand, and unexpected recoveries on the other, it will still remain to be a source of perplexity in all desperate cases. In solving this perplexity, the occasional presence, or the contrary, of bile in the *ejecta*, is an element of far too great importance to be lost sight of. Where it was at length determined, after due deliberation, to risk the operation, it might be worth considering whether the chief peril attaching to its performance might not be averted by proceeding in the mode now practised in the first steps of the operation for the extirpation of ovarian cysts,—namely, by securing the sac to the walls of the belly before making the necessary opening for the discharge of its contents.

Park Street, Bristol.

OBSERVATIONS ON HYDATID DISEASE OF THE LIVER.

By P. M. DUNCAN, M.B., LONDIN., F.G.S.,

PHYSICIAN TO THE ESSEX AND COLCHESTER HOSPITAL.

PART II.*

THE last communication referred to the development, generation, and decadence of acephalocyst hydatids; in the present their distribution, symptoms, and treatment will be considered.

Although hydatids are most frequently found in the liver, yet the spleen, kidneys, lungs, and brain are obnoxious to their attacks; and there is hardly a tissue in the body which has not, at some time or other, been the seat of these pernicious parasites. The superficies of the body, consisting of a greater or less amount of cellular tissue supporting the true skin, is, especially after severe contusions, liable to be affected by acephalocyst hydatids. The nidus of the parasite is in the cellular tissue beneath the basement membrane of the true skin.

Case.—A man, aged 46, of intemperate habits, fell backwards whilst carrying a heavy weight, and struck his back against a log of wood. He experienced considerable pain beneath the angle of the right scapula, where there were evidences of a considerable bruise for several days. After the lapse of a week, the tenderness and pain having subsided, he noticed that the swelling was not decreasing so rapidly as it had done. After a while a decided tumour appeared at the above spot, grew rapidly, gave him no pain, and produced no constitutional disturbance. He was admitted into the Colchester Hospital, under the care of my colleague, Mr. Waylen, some months after the accident. A tumour as large as an infant's head was found below the right scapula; its form was rather irregular; it presented the sense of fluctuation very indistinctly; the skin was moveable over it, and manipulation produced no pain. An incision let out pus and many acephalocyst hydatids, some collapsed, others globular and containing secondary cysts. Cysts continued to be discharged for a fortnight; no constitutional disturbance followed, and the man was discharged cured.

It would appear that the parasite found a proper nidus in a bloodvessel implicated in the contusion; that it grew gradually; and at last, owing most probably to those intrinsic changes described in my last paper, suppurated.

Usually considerable constitutional disturbance follows the opening of superficial hydatid sacs, on account of the sloughing of the external fibrous tunic. It is to be remembered that the older the hydatid the thicker is the fibrous coat; and that the vascularity of this last tissue decreases with its thickness. Open, then, all tumours made out to be hydatid, occurring in the superficial cellular tissue, as soon as possible.

* Concluded from page 654, No xxiv., of last volume.

The buttocks are frequently the seat of hydatids, after blows, kicks, or violent contusions; and from the depth of the cellular tissue, very serious consequences follow occasionally surgical interference. I would suggest that the fibrous sac be removed, to prevent its sloughing.

Acephalocysts are very seldom found in the muscular system, but in bone they exist more frequently. Stanley, in his admirable work on the diseases of bones,* gives the best description of the disease. He writes (page 189):—"Globular hydatids have been found in bones of every form. Usually they have been developed only in a single bone. In a case, however, which occurred in St. Bartholomew's Hospital I found them in two bones—the os innominatum and sacrum; and, in the history of another case, it is stated that the entire osseous system was beset with tumours containing hydatids. The development of hydatids in bone has not, in general, been accompanied by pain or irritation of any kind; but, as the consequence of their increasing number, the following changes have occurred in the bone itself:—First, the expansion of its walls, either generally, so as to produce an enlargement of the whole bone, or in a limited extent, so as to produce a well-defined tumour; then absorption of the walls, in one or more situations, has ensued, permitting the escape of the hydatids from the bone into the soft parts around it. The presence of the hydatids in the soft parts contiguous to the bone has excited suppuration, so that on puncturing the swelling they formed; puriform fluid, mixed with the hydatids, has been discharged. Further, it has happened that during the absorption of the walls of a bone filled by hydatids, a slight muscular effort caused the bone to snap, and, in such a case, the occurrence of the fracture afforded the first indication of serious mischief in the bone. Hydatids developed in other organs are contained in adventitious cysts; and there appears to be a similar structure connected with their formation in bone, a smooth white membrane being found closely adherent to the walls of the cavity in the bone in which the hydatids are lodged.

Case.—A woman, aged 54, was admitted into St. Bartholomew's Hospital, having a globular and somewhat pendulous tumour, about the size of the closed hand, situated upon the nates, directly over the right sacro-iliac symphysis. She stated it had been five years in progress. A few weeks before her admission it had been punctured, and purulent fluid, mixed with hydatids, was discharged. The tumour again enlarged to its original size, and on being punctured a second time, only purulent fluid escaped. A free incision was now made into the tumour, with the effect of discharging a large quantity of hydatids, with fragments of bone and purulent fluid. Severe constitutional derangement ensued, which in a few weeks was fatal.

On examination numerous globular hydatids were found in the interior of the right os innominatum, and also within the sacrum. In both these bones the cancellous texture had disappeared, and the surrounding

walls were much thinned, and widely separated from each other, a large cavity being thus formed in the bone, in which the hydatids were lodged. There were also apertures in the walls of each bone, through which some of the hydatids had escaped into the surrounding soft parts. The cavity in the sacrum communicated also with the spinal canal, in which there were numerous hydatids. A smooth white membrane lined the cavity in the os innominatum and sacrum. There was a mass of hydatids between the extensor muscles of the spine, which was unconnected with the contiguous bones, and another mass in a cyst attached to the ovary.

The foregoing case shows the uncertainty there may be in the diagnosis of the tumour produced by hydatids, which have escaped from the bone where they were formed, into the parts around it. The hydatid cyst protruding from a bone, forms a soft elastic swelling, which has been mistaken for the tumour of malignant disease; and when, by the absorption of their membranous cysts, the hydatids have escaped into the surrounding cellular tissue, exciting suppuration in it, the swelling has presented the characters of chronic abscess. When, owing to the increasing accumulation of hydatids in a bone, its walls become thinned and expanded, the tumour may then communicate to the fingers the peculiar crackling sensation which belongs generally to osseous cysts with thin sides. But, in some instances, the walls of a bone filled with hydatids do not become thinned, they simply expand in such a manner as to form a circumscribed unyielding tumour, having the characters of an osseous growth from the bone. Such was the nature of the tumour, and, consequently, the difficulty of its diagnosis, in the remarkable case recorded by Mr. Keate, of an enormous collection of hydatids between the two tables of the frontal bone. In this case the outer table was removed; the hydatids were carefully removed, and the wound filled with lint, dipped in a solution of sulphate of copper. The cavity filled up by granulation, and the patient recovered. Stanley proceeds:—"The treatment suited to a case of hydatids in bone will depend on the situation and extent of the disease. If the hydatids occupy the larger portion of a bone, and have occasioned much destruction of its walls, the removal of the entire bone, or of the limb in which the disease is situated, may be necessary. But there are cases in which it is expedient to scoop out the hydatids from the cavity in the bone; and in treating such cases it should be borne in mind, that the bone is not diseased, otherwise than as its walls are expanded, or a part absorbed, consequently that no more of the bone will require removal than is sufficient to effect the dislodgement of the hydatids; for when this has been done, and astringents or stimulants have afterwards been applied to the bone, no reproduction of the hydatids has ensued. Healthy granulations have filled the cavity in the bone, and the wound has healed soundly over them."

Acephalocyst hydatids have been found in the sheaths of tendons, where they have been treated as "ganglia." Synovial membranes do not appear to form a nidus for

* A "Treatise on the Diseases of Bones." By Edward Stanley, F.R.S.

the parasite. The cysts found in the larger joints are not acephalocysts.

In the substance of the brain we occasionally meet with large solitary acephalocysts, with a very thin external fibrous coat. The compound parasite is very rare. All parts of the brain are obnoxious to the attacks of hydatids; the morbid phenomena differ with the seat and rapidity of the growth of the cysts. The choroid plexuses are frequently the seat of vesicles or cysts, which, although they are called hydatids, are not parasites, but simple cystic degenerations of the acini and villous appendages of the plexus; in aged persons they usually contain yellowish-looking sand, and vary in size from that of a pin's head to that of a bean. Rokitsky speaks as to the rarity of the occurrence of acephalocysts in the spinal cord; their nidus is even outside the dura mater. In one case the cyst forced its way into the canal of the arachnoid. Even in the large nerves they rarely exist. Hydatids have been removed by operation from beneath the conjunctiva; and they occasionally exist in the orbital cellular tissue.

*Case.**—Chas. Rowell, 42 years of age, was admitted under my care into the London Ophthalmic Infirmary, on the 3rd of January, 1820, with protrusion of the globe from the orbit by a deep-seated tumour, which had been growing seven years. When this patient was admitted into the infirmary, the tumour had advanced so far between the upper and inner portion of the eyeball and the eyelid, as to have thrust the globe completely out of the orbit. The upper lid, greatly stretched and inflamed, covered the eye and the tumour; the lower was completely everted, and its membranous lining appeared as a thick fleshy mass. The conjunctival covering of the globe was thickened by chronic inflammation, the consequence of exposure. The structure of the eye was uninjured; the pupil round, and about in the middle state; the iris motionless. Vision was destroyed. The tumour was firm, and apparently affixed to the orbit; it afforded, on pressure, an obscure sense of fluctuation. To relieve the distension and pain, and acquire some further insight into the nature of the disease, a puncture was made into the most prominent part of the swelling, and about a dessert-spoonfull of clear watery fluid escaped; considerable diminution of suffering ensued. When I examined the part, two days afterwards, I found a soft, opaque, white substance in the puncture, and proceeded to remove it with a pair of forceps; it proved to be an hydatid, and a few others escaped when pressure was made on the swelling. Some more came away on the following day, and I afterwards cleared out the whole collection, amounting to half a teacupful, by enlarging the puncture, and injecting water forcibly into the sac. Inflammation and suppuration of the cyst followed, without much pain. The discharge then gradually diminished, and the opening closed in about a month. The eye returned to its natural situation, and all uneasiness ceased. In March a little motion of the iris, and slight perception of light had returned.

Hasse declares that the muscular structure of the heart is occasionally the seat of parasites, but not of the

acephalocyst hydatid. In animals this is not true. I have already noticed Andral's case, which proves the presence of hydatids in the blood-vessels, and have noticed their influence upon the calibre of the affected vessels.

Lung.—After much constitutional disturbance, great and violent cough, with or without hæmoptysis, collapsed acephalocyst hydatids are occasionally expectorated. They may have been originally deposited in the parenchyma of the lung, or as is most frequently the case, may have passed by the process of ulceration, from the convex surface of the liver into one of the bronchial tubes. In the first instance, the acephalocysts are not tinged yellow by the bile, neither are they expectorated in any quantity at any one time; the reverse is the case when the liver is the organ primarily affected. Andral once found nearly the whole of the inferior lobes of both lungs transformed into capacious sacs, but usually one lung is alone affected; the acephalocysts, about the size of pigeons's eggs, being surrounded by a dense and laminated protective sac, formed from the parenchyma of the lung, are very firmly fixed. In cases where acephalocysts have been expectorated, a communication between a bronchus and a suppurating sac is found, which may still contain perfect hydatids floating in pus. The amount of condensation around the sac is strangely small, and it is quite the exception to find any inflammatory action going on in their neighbourhood. Death appears to be caused by pressure upon, and occasionally ulceration into, the bloodvessels, by great encroachment upon the region of the heart, by gradual destruction of the affected lung, by abscess and its consequences, and by simple exhaustion. A solitary example is given by Hasse, of an hydatid detached through inflammation making its way into the pleural cavity, leaving in the upper and middle lobes of the right lung a cavity in communication with the bronchia, and determining pneumo-thorax. Both simple and compound acephalocysts are found in the lungs; they appear to choose the inferior lobes and that part furthest removed from the pleura for their seat, their diagnosis is therefore very difficult. Dyspnoea is the earliest symptom and continues to the end; it increases steadily and is relieved to a certain extent, by the expectoration of the parasites. Occurring without any other symptoms—without any inflammatory attack, the dyspnoea is hardly to be accounted for by the physical signs. The cysts are too deep to influence percussion at their early stage, and on account of the supplementary character of the vesicular murmur in the upper regions of the chest, their presence entails; the patient is usually said to be the subject of emphysema. But after a while most fearful bronchitic irritation and cough set in, the dyspnoea increases, and low down in the posterior regions of one or both sides of the chest, we may detect slight and diffused dulness on percussion. The vocal fremitus is diminished in intensity, and hæmoptysis occurs after a while; the heart may be displaced and the affected side bulged out; there is no prominence, however, of the intercostal spaces, and

* Lawrence. Med. Chir. Trans., Vol. 17, p. 48. See Middlemore, vol. 2.

consequently no evidence of empyema. At the seat of dulness, the natural vesicular murmur is, as this increases, masked by blowing or tubular sounds, accompanied by large moist râles. If the hydatid sacs ulcerate into a bronchus, their contents are gradually expectorated, a singular change of the physical signs resulting, mucous râles are heard over the whole of the affected side, and gurgling at one or more spots; the dulness on percussion has vanished, tympanitic resonance being produced; the tubular breath sounds have become amphoric, and various degrees of pectoriloquy exist. These physical signs vary, however, with the amount of the contents of the cavity. I am not aware of any but a fatal result in these cases, but when the liver is primarily affected and the hydatids ulcerate through the lung, recovery is by no means unusual. Hydatids in the lung, which have not attained to very great size, cannot be diagnosed; the case may be taken for one of emphysema, complicated with sub-acute bronchitis; when, however, the dulness on percussion is at the inferior part of the lung, the rest of the organ being unusually resonant, the opinion cannot hold. Pleurisy is contraindicated by the transmission of the vocal fremitus. Cancer of the lung, of the infiltrated kind, and unaccompanied by enlarged bronchial glands or mediastinal tumour, is distinguished by the almost invariable flattening and retraction of the affected side. In hydatid disease the side is enlarged; in both diseases hæmoptysis, pain, cough, and scanty expectoration at first occur, but in cancer the constitution suffers most. The nodular form of carcinoma cannot be distinguished. In a case with which I was familiar, nodules of melanosis were deposited here and there in the parenchyma of the inferior lobes of both lungs. During life a careful stethoscopist distinguished the presence of some portions of tissue more dense than the surrounding lung, in fact, all the presumed physical signs of hydatids existed. When cancer is combined with tumour, the mediastinal dulness is so increased, and the signs of pressure upon the great vessels, œsophagus, and bronchi, are so decided that the differential diagnosis is of no difficulty. In cases of chronic pneumonia, the dulness on percussion does not gradually increase as in hydatid disease, remedies have more effect in allaying the cough, and hæmoptysis is rarer than in the affection before us; the history of the case is of great assistance in the diagnosis. With such very negative evidence as the above, we must esteem the diagnosis of hydatid disease of the lung to be almost impossible, except under very favourable circumstances. When acephalocysts are deposited in the tissue of the liver, near to its convex and superior surface, their growth soon brings them in contact with the fibrous envelope of the organ, the diaphragm becomes adherent, and the pleural layers also, most distressing lung symptoms ensue, and after a severe fit of coughing the patient expectorates pus, collapsed hydatids, and, sooner or later, bile.* Recovery is very usual, all the symptoms being

relieved by the evacuation of the parasites, suppuration of the sac appears to occur, the adherent diaphragm and pleuræ are pierced, abscess of the parenchyma of the lung follows, bursting at last into a bronchus, the abscess determines a communication between the sac and the air. Hasse once found a shrivelled acephalocyst beneath the costal pleura.

Liver.—Hydatids affect the liver in preference to any other organ and are found in all parts of it, rarely in the left lobe and most commonly in the right, where they attain to their greatest size; they are to be met with deep in the parenchyma or superficially and pushing forwards the capsule of the organ, and generally exciting adhesion between it and the side. One cyst or several may exist; they are found of all sizes, from that of a nut to a size which enabled them to hold several pints of fluid. Those deposited deeply cause absorption of the substance of the liver in their immediate neighbourhood by the pressure coincident with their growth, and after a while reach the surface. When the acephalocyst has become superficial, that part of it which is in contact with the capsule of the liver has no external fibrous sac, it is simply covered by the capsule and that part in contact with the liver still retains its accessory covering. At first little inconvenience results from the presence of hydatids in the liver, but as they increase in size, the edge of the liver descends below the cartilages of the ribs, and the patient suffers from dyspepsia, and pain in the shoulder and side. Jaundice rarely occurs until a late period, nor does the portal circulation suffer, except the hydatids are large or so numerous as to cause pressure upon the great venous trunks. Tumour below the rib in the right hypochondriac region, and elevation and expansion of the lower cartilages are the first physical signs of the disease; the tumour is ill defined, moves with inspiration and expiration, is frequently painful to the touch, and when percussed gives a most peculiar vibratory thrill to the finger, so unique as never to be forgotten if once felt. From causes already explained, the tendency of the tumour is to enlarge, the liver increases in size, the belly feels hard and nodular, and after a while the portal and systemic veins suffer, the case ending by effusion into the cavity of the peritoneum with oedema of the legs, accompanied oftentimes by displacement upwards of the heart and lungs; or, the tumour, owing to changes in its walls, already alluded to, may burst into the transverse colon, or into the duodenum, into a gall-duct, or the gall-bladder. A natural cure is frequent under these circumstances, as also when the acephalocyst opens by ulceration through the umbilicus, (see Case in Paper I.) or when its contents pass into a bronchial tube. But when the hydatid ulcerates and opens into a bloodvessel, into the cavity of the peritoneum—unless the structure of this membrane be very much covered by false membranes, or into the pleural sac, recovery is most unusual. The tumour, as has been proved by Case 6, may burst in two directions at once—into the bronchus and into the intestine. Recovery ensues, rarely however, by the nutrition of the acepha-

* See Dr. Durrant's case, *Provincial Medical and Surgical Journal*, No. 5, 1851; my case, *Ibid.*, No. 24, 1850; and Dr. Todd's lecture, *Med. Times*, January 3, 1852.

locyst being suspended, the fluid is absorbed, the fibrous sac contracts, and the acephalocyst is folded up within it. (See Case 5.)

When a tumour appears in the right hypochondrium, unaccompanied by pain and severe constitutional disturbance, not preceded by inflammatory symptoms and fever, and possessing the peculiar vibratile thrill on percussion, moving also with the efforts of respiration, we may safely diagnose hydatid tumour of the liver. Abscess of the liver is preceded by constitutional disturbance of the severest character, and in this climate, in my experience, is much rarer than hydatid disease. Swelling around the cartilages of the lower ribs may simulate the disease for a time, but pain exists, and there is no vibratile thrill. Abscess high up in the abdominal walls, or within the sheath of the rectus, is distinguished by the previous history of the case, the vague feeling of fluctuation, and the non-movement with the expiratory and inspiratory efforts. [Malignant disease of the liver rarely takes on the form of tumour; usually the patches of the adventitious deposit are not raised above the surface of the organ, indeed their centre is usually depressed. An enlarged and distended gall-bladder is likely to be mistaken for hydatid tumour; but the swelling commences near the median line, is accompanied by jaundice and much constitutional disturbance, and the edge of the liver can be traced to its margin. By keeping up the powers of nutrition we may hope to arrest for a time the march of hydatid disease. Turpentine, iodine, and mercury may be given in small and repeated doses with effect; but I know of no instance of a cure. The evil day is put off for a while, and not for ever. We must look to surgical interference for aid; for, except under the most unfavourable circumstances, puncture of the acephalocyst is a safe cure. When the health is at a low ebb, and the tumour large and old, the operation will nearly always fail; but it is quite justifiable if the tumour be recent, not very large, and if the health be not much depressed. When a large, and consequently old, sac is punctured, the fibrous envelope usually sloughs; or, at any rate, so much suppuration occurs from its inner surface as to destroy life; but when the contents of a moderate-sized sac are let out the fibrous envelope collapses to a considerable extent; and on account of its being recent, tolerably thin, and not affected by those intrinsic changes alluded to in my last communication, is not liable to slough. It is of the greatest importance that before an acephalocyst of the liver is punctured it be satisfactorily determined that it adheres to the parietal layer of the peritoneum, that there will be little danger of any of the fluid escaping into the peritoneal cavity. Unfortunately this can rarely be done; but it can, with certain aids, be brought about. It is usual for the acephalocyst to be adherent; its increased size and constant motion upwards and downwards tend to the production of false membrane. Some surgeons, therefore, bandage the patient, to keep the tumour steady, and open it with a trocar, and enlarge the opening in the skin and superficies afterwards. A large opening into the sac is useless;

indeed, absolutely dangerous; for a little manipulation will remove any secondary cysts from the opening, and the danger of some of the fluid coming in contact with the peritoneum is in an exact ratio with the size of the incision. Others open by cautery by potassa fusa; and to this plan I certainly adhere; the risk of non-adhesion is done away with, and time is no great object. The simple serous cyst, a serous sac containing a clear watery fluid, is occasionally met with in the liver; it possesses none of the characters of the parasitic acephalocyst.

Acephalocysts are found in the spleen, in the sub-peritoneal cellular tissue, and in the substance of the kidney. Usually when an acephalocyst exists in the spleen there is another in the liver; but it does occasionally happen that such is not the case. Rokitansky says:—"It rarely attains the size it reaches in the latter organ, but is otherwise not distinguished by any peculiarity." In my third case hydatids were found in the omentum; but there were others in the liver. Beneath the peritoneum they grow with great rapidity, and attain an enormous size; and are not to be mistaken for simple non-parasitic growths. In the kidney acephalocysts have grown to the size of a child's head. They may burst either into the colon, and their contents be passed out with a motion, or into the pelvis of the organs; and the fluid and secondary cysts will pass into the bladder, and be ejected with the urine. Rokitansky denies the existence of acephalocysts in the bladder; they are occasionally found in the cellular tissue covering it, and also in the cellular tissue around the rectum. In the female, when they occur in these positions, they greatly complicate the diagnosis of ovarian dropsy. Hydatids have been found in the substance of the uterus. It need hardly be remarked, that the so-called hydatids of the placenta are not acephalocysts, but simple serous vesicles, derived from the villi of the chorion. The cysts in the kidney which are most commonly found, upon examination, are proved not to be acephalocysts. Such is the case in cystic disease of the breast.

Beautiful as these acephalocysts are in structure, their presence in the system is most baneful to life; rapid in their growth, and influencing all parts within their range by their mechanical effects, they, by their very existence, denote a low and ill-nourished constitution. We must, first of all, endeavour to increase the powers of assimilation, and then consider whether there be any drug capable of arresting their growth and determining their absorption. I can give but little assistance from my personal experience. Oil of turpentine in small and repeated doses, and inunction of strong iodine ointment, certainly arrested the progress of the disease in my fourth case, which came under my care two years ago, and is now alive, and in a better state of health.

Above all internal remedies stands surgical interference. From what I have seen, I believe that the sooner a tumour, declared to be hydatid in its nature, is opened, the better; and I am satisfied, that as medical statistics are more carefully collected, that the above opinion will be proved to be correct. Of the etiology of acephalocyst hydatids we are very ignorant.

Rokitansky denies the coexistence of hydatids and tubercle in the same economy. Andral and others have seen them together, and therefore multiply the Professor's dogmatic assertion.

January 17, 1852.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CASES ADMITTED UNDER LANGSTON PARKER, ESQ.

Extracted from the Clinical Records,

BY W. J. MOORE, ESQ., RESIDENT SURGEON.

Recovery after very Extensive Injuries.

To prognosticate correctly the termination of disease very frequently requires great amount of discrimination and tact, not to be acquired by a corresponding experience; and this remark also is applicable to injuries requiring the aid of the surgeon. Perhaps the most important point to take into consideration is the age of the patient, as it often is found that the same amount of injury which a young subject rapidly and easily recovers from would prove fatal to a person of more mature years; and indeed it is daily noticed that the younger a patient is, down to a certain age, with so much more facility will he rally after extensive injuries. At the same time it must be remembered that children of two or three years old should form exceptions to this remark. Should a person in good health meet with extensive injuries, and have "youth on his side," he has, at least, "half the battle;" and in exemplification of this remark a case is brought forward which lately occurred in the practice of Professor Parker, at this hospital:—

George Hudson, aged 13, was brought to the Queen's Hospital on the 8th of August last, having some ten minutes before been caught by one of the leather bands which are used to impart motion to the grindstone in one of the adjacent sword manufactories. He was carried round the stone before the machinery could be stopped; and on examination at the hospital the following injuries were apparent:—Bruise of both legs, the right being most hurt; both thigh bones were badly comminuted in their whole extent of shaft, the knee-joints, however, being intact; comminuted fracture of the right forearm (ulna and radius), partial dislocation of the wrist; several cuts and bruises on the fingers; extensive laceration of the left forearm and arm, the humerus being broken in several places, and the ulna and radius being in a still worse condition; the elbow-joint laid open; several superficial cuts and bruises on the head.

There was, notwithstanding these injuries, a partial sensibility present; but the surface was cold, the pulse intermitting, and the countenance pallid; concussion, in a minor degree, being established. There had been little or no bleeding from the lacerated parts, and the brachial artery although bruised, was not quite torn through. The laceration of the integuments extended

quite into the axilla, but on the outer side, over the deltoid, it was freer from injury, and afterwards served as a flap on removal of the limb.

The patient was placed on a bed, and some warm tea given immediately; and in the course of an hour the pulse was much stronger, and the surface warm. The left humerus was then sawn off very near the head, but the shoulder-joint was not opened, and the flap made from that portion on the outside, before mentioned, as having escaped with little injury. Three ligatures were applied, and the stump dressed in the usual manner. Two straight splints were used to keep the thighs in apposition, aided by four shorter ones round the fractured parts. The arm was reduced and bound up, and the head shaved.

In the evening the boy seemed going on well. He was sensible, but did not complain of pain; and there was some difficulty in getting him to answer questions. The pulse counted 100, and had tolerable force. The head was hot and the conjunctiva congested. He was ordered a dose of calomel.

August 9th. *Morne*.—Has been muttering much during the night, but is again sensible; the pulse counts 120; head is hot; bowels not opened, but tongue clean. Half an ounce of castor oil directly. Cold to the head.

Meridie.—Oil has not operated; intellect does not seem so clear as it appeared this morning; pulse 120. Rept. Ol. Ricini.

Vespere.—Has been gradually becoming worse; breathing and heart's action are very quick; head very hot; muttering delirium; pulse 120; bowels not moved. Applicant. Hirud., vj., tempor.; Hab., gtt. j. Ol. Croton statim.

12, P.M.—The croton oil has procured copious stools; there is still muttering delirium present, and in most respects he remains in *statu quo*.

10th.—There has been much wandering during the night, but this morning he is again sensible, the pulse counting 100, and the head less hot; breathing quiet. In all respects evidently better.

11th.—Sensible, and now begins to complain when the splints are adjusted, or the stump dressed; bowels moved to-day without medicine.

12th.—Going on well; suddenly this afternoon he had an attack resembling syncope, all the characteristics of such a state being present. The strong ammonia was applied to the nape of the neck, which produced almost instant reaction.* In the evening much headache was complained of, with much general irritability, and three leeches were applied to the temples, with benefit.

13th.—Going on well. The inner portion of the integument next the axilla looks red and inclined to slough, and fears were entertained lest the artery should be opened by that process. Instructions were given to the attendant, and instruments kept at hand ready for such an occurrence.

14th.—Going on well.

15th.—The slough has become detached this morning

* The application of the strong ammonia to the back of the neck and spine will be found one of the most serviceable remedies in cases of fainting, concussion, hysterical insensibility, and the like. Care, however, must be taken in its application lest it should escape and interfere with the respiration of the patient.

without any hæmorrhage. He is in all respects going on well.

It will be needless to relate the farther daily history of the case. A small abscess formed at the lower border of the axilla, which required the lancet; excepting which he had no untoward symptom. He was eventually discharged cured, October 31st, having attended during the last two weeks as an out-patient. He now walks well, is but slightly lame, has perfect use of the remaining arm, and attends one of the neighbouring schools, looking and feeling quite well.

In the treatment of this case the greatest care was requisite to maintain the proper length of the legs, but perhaps the most trouble was experienced in keeping the fractured arm in place, for when the boy was getting better he continually threw the limb about, and, moreover, became so irritable that he would not lie still a moment; he was, however, discharged, undoubtedly in as satisfactory a state as could well be wished.

Provincial Medical & Surgical Journal.

WEDNESDAY, FEBRUARY, 4, 1852.

THE Draft of the Bill for reforming the profession, as printed in our last number, has given more satisfaction, as far as its general principles are concerned, than we could possibly have anticipated; indeed, we have heard, as yet, of no opposition, excepting as to some minor points of grievance, which were really never intended. Foremost amongst these is that contained in the 22nd clause, which was never meant to be retrospective, and which must certainly be altered so as to exclude from its penalties those Licentiates of the Hall and others who have long, in common parlance, enjoyed the title of surgeon. It would be hard upon those gentlemen to compel them to drop the title; nor was such ever the intention of the framers of the Bill. There is also an omission in the same clause (which was a very recent addition to the Bill), of all allusion to Glasgow, Aberdeen, and St. Andrews; these have long been allowed to grant degrees in medicine, and, consequently, great injustice would be done to the holders of such degrees if they were prevented from assuming the titles attached to them.

Our correspondent, Mr. WILLS, whose letter is given at page 82, proposes some questions which we will, as they have also been repeated by others, endeavour to meet seriatim:—

1st. As to the payment of £10. This is an open question, which must be left to the decision

of the Committee of the House of Commons, (if it comes before that body,) in its progress through its various stages in Parliament.

2nd. The registration fee of 20s. is too much certainly as a simple payment for registration; but Mr. WILLS seems to have forgotten that the surplus is to be applied to purposes which are undeniably good; and also one half to form the Provident Fund.

3rd. As to the restrictive clause upon the practice of druggists, it has been supposed by the framers of the Bill that however much it may be the wish of the profession, it is quite impossible to persuade the House of Commons to pass such a clause as would have the effect desired by Mr. WILLS, and that even if passed it could have no greater effect than the present Apothecaries' Act, which is wholly inoperative, like many other laws which are in opposition to the voice of public opinion.

With regard to the two last questions they are points which have not yet received the attention which they deserve, but of course they must be settled before going to Parliament. We are only surprised that there has been so little omission of important points in the Bill. The chief difficulty appears to us to be the settlement of the claims of the Apothecaries' Company and the holders of their licence without the diploma of the College of Surgeons. It appears that after the passing of this Bill medical men will all be classed as Physicians, Surgeons, or Licentiates in medicine, surgery, and midwifery; but under which of the two last must those be included who are simply Licentiates of the Apothecaries' Company? We think they should be at once admitted to the licence of the new Board, which would destroy for ever the title of Apothecary, a title which has now become offensive to all, because it has been made a term of reproach for many years past. The examination by the Apothecaries' Company has always been a severe one as compared with that at the College of Surgeons, and therefore we think that the licence of the new Board might at once be accorded to them without injustice to the public or the profession.

If it be a peculiar characteristic of the medical profession that novel ideas and new appliances and means of study are received with distrust, or, at best, but slowly appreciated, it cannot be affirmed that this scepticism is altogether an evil.

It leads inevitably to the abolishment of many visionary theories, which a less reflective tone of mind would cause to be adopted on insufficient premises; while anything really true and valuable becomes the more indelibly fixed upon the attention from the very tardiness with which its claims are admitted. Many of our readers can doubtless remember the indifference and oftentimes ridicule which met the first introduction of LAENNEC's splendid discoveries. But now, how universal is the acknowledgment of the merits of auscultation, and how implicit is the reliance upon the information which it affords, among those who are thoroughly acquainted with its principles and practice.

The introduction of Microscopic aid in the investigation of disease is no exception to the general rule. As in the case of the stethoscope, there are multitudes who yet regard it with indifference; and not a few "practical" men, as they delight to call themselves, who utterly scorn such assistance. They will not indeed go so far as to deny the important services which the microscope has conferred upon the sciences of anatomy and physiology; but they choose to doubt whether any real advantage will accrue from its use in the investigation and treatment of disease. To point out the fallacy of such opinions, and to advocate a more general resort to this additional means of pathological investigation is the object of the present cursory observations.

In order to demonstrate the reality of the benefit derived from microscopic research in the treatment of disease, let us select a class of maladies in which that benefit is most conspicuous,—viz., those of the urinary organs. For example, a patient complains of obstinate irritative dyspepsia. He is low spirited, morbidly irritable in temper, emaciated, and intolerant of exertion, mental and bodily. He passes frequently either a clear urine, which to the unassisted eye appears perfectly healthy, or urine depositing a sediment which, examined by ordinary tests, is believed to consist entirely of lithate of ammonia. But the microscope display abundant crystals of oxalate of lime; and thus gives a clue to an otherwise obscure train of symptoms, and directs to the most successful treatment. Again, in somewhat similar cases, there is the addition of unintelligible cerebral disturbances, verging in some instances upon insanity; here also the microscope, by the detec-

tion of spermatozoa, declares at once that the patient is labouring under spermatorrhœa, and thereby leads to the adoption of the appropriate means of cure.

But it is in those several renal lesions which are classed indiscriminately under the term "BRIGHT'S disease," that microscopic inquiry leads to the most useful results. These lesions of the kidney are now well known—thanks to the interesting labours of Dr. GEORGE JOHNSON—to depend upon two distinct morbid processes, one inflammatory, and, if detected early, amenable to treatment, the other, a fatty degeneration, and all but hopeless as to its ultimate results. How important is it to determine whether a given case is one in which the treatment of inflammation will be serviceable, or whether it is one, on the other hand, in which such treatment will prove highly prejudicial. This most necessary information is to be acquired only by the help of the microscope. The presence of simple tubular casts in the urine encourages the practitioner to hope for amendment; while, on the other hand, the presence of oil globules enclosed in them admonishes him that his treatment can only be palliative.

We do not insist upon the microscopic diagnosis of malignant growths, although we believe that in competent hands the distinction between cancerous and non-cancerous structure may be determined with a certainty otherwise unattainable. Enough has, we trust, been adduced to show that histological knowledge, as developed by the aid of the microscope, is not a merely optional medical accomplishment, but is positively indispensable to the due appreciation of some, even of the least, rare diseases to which the human frame is subject. Another example or two will, however, give additional force to our observations.

A scalp eruption may assume such an indefinite appearance, that it is difficult, by simple inspection, to determine its precise character. The discovery of the parasitic fungus—the *Achorion Schoenleinii*, at once points out true favus—a communicable disease.

Dr. HUGHES BENNET mentions the case of a girl who was supposed to be labouring under hæmoptysis. But for the assistance derived from the microscope, a serious impression would have been received from the symptoms; however, an examination of the sputa proved the blood globules to be those of a bird, and the

patient was thus convicted of imposture. Similar instances might be multiplied to any extent.

It is probable that one of the chief obstacles to the general introduction of the microscope into medical practice is the expensiveness of the instruments; it should be known, therefore, that a serviceable French instrument is to be purchased for seven pounds, and that for less than twice that sum one can be obtained which combines every requirement that the medical student can desire.*

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

The following resolutions on the subject of homœopathy were unanimously passed at the annual meeting of the Birmingham Midland Counties Pathological Society, held on January 8th, 1852:—

“That the following class of practitioners are unqualified to become or continue members of this Society:—

- “1. Those who practise homœopathy exclusively.
- “2. Those who practise homœopathy in conjunction with other systems of medicine.
- “3. Those who, under various pretences, meet in consultation, or hold professional intercourse with, those who practise homœopathy.

“That a copy of the above be sent to the *Provincial Medical and Surgical Journal*, *Lancet*, and *Dublin Quarterly Review*, requesting its insertion.”

METROPOLITAN SANITARY ASSOCIATION.

[At the request of the Honorary Secretaries to the Acting Committee of the Metropolitan Sanitary Association we insert the following report, made to the National Academy of Medicine, Paris, with the resolutions adopted thereon:—]

QUARANTINE LAWS.

Translation of a report by MM. MAGENDIE, LOUIS, and LONDE (Reporter), to the French National Academy of Medicine, on a work by JAMES GILLKREST, Esq., M.D., &c., Inspector-General of Army Hospitals, entitled, “*Is Yellow Fever Contagious or Not?*”

“You have charged MM. Magendie, Louis, and myself to render an account of a work by Dr. James Gillkrest, Inspector-General of Army Hospitals, in the service of Great Britain; which is entitled, “*Is Yellow Fever Contagious or Not?*”

* We have recently procured a very fine instrument from Pillischer, 338, Strand, consisting of a brass tube and pillar, with fine adjustment, two eye pieces; an inch, half-inch, and quarter-inch object glasses; condenser, in mahogany case, for £12. 10s. This instrument we can strongly recommend for its accurate defining powers and finished workmanship.

“The history of Yellow Fever is treated by M. Gillkrest with an erudition which it would be difficult to find equally complete elsewhere. After mentioning observers and monographers, describers of Yellow Fever, beginning with Hippocrates, who speaks of a fever characterised by yellowness of skin, and black vomit, M. Gillkrest arrives at these conclusions.

1st. That the Yellow Fever of America, and that observed in the south-west of Europe, especially in Spain, are identical; an identity acknowledged by all authors, with the exception, perhaps, of our colleague, M. Rochoux.

2ndly. That this disease existed in the Antilles before 1793, and in the Spanish Peninsula before 1764.

“M. Gillkrest next relates a great number of facts, establishing:—

1st. That Yellow Fever, or at least its pathognomonic symptoms, have shown themselves at very remote points of the globe, and that they appear to be then developed uniformly under accidental or local conditions, so strongly marked as to exclude all idea of importation, in the true meaning of that word.

2ndly. That sporadic cases of Yellow Fever present themselves, in ordinary years, in the localities where this disease has prevailed in an epidemic form. M. Gillkrest considers that this second inference is established by a certificate by the Medical Officers, who, on the 13th of April, 1829, at Gibraltar, declared—after having read with the greatest care thirty-nine cases extracted from the records of the Civil Hospital—that the symptoms detailed in these cases were perfectly identical with those observed in the epidemic which prevailed in that garrison in the latter part of the year 1828.

“Having established these fundamental points, M. Gillkrest arrives at the grand question—contagion.

“The Author establishes, by numerous well-selected and incontrovertible proofs, that Yellow Fever is not contagious under any circumstances, not even in the case of crowding, in this disease, whether of the dead or of the living; that the removal of the individual from the influence of the local causes which produce this affection is the fittest means of preventing its extension; and, lastly, that the cordons called sanitary, and quarantine measures, far from arresting Yellow Fever, on the contrary, favour its extension by confining the population within the influences of the local causes which give it birth.

“Such, gentlemen, is the work on which we have to report. Mr. Gillkrest, in crowning services which do him honour, and which on more than one occasion have been extended to our fellow-countrymen brings to bear upon the question of contagion in Yellow Fever (a question so intimately connected with the most important interests of mankind,) the fruits of a long experience, as was done formerly by our intrepid and ever to be regretted Chervin.

“This communication of M. Gillkrest, which has already received the full approval of the General Board of Health in London, has reached us most opportunely at the moment when a Congress is assembled to suggest, no doubt, important modifications in our sanitary laws; consequently, gentlemen, your Committee has the honour to propose:—

"1stly. To thank the Honourable M. Gillkrest for his interesting communication.

2ndly. To transmit his work to M. The Minister of Commerce, in order that, in conjunction with the numerous documents on this subject already in possession of the Administration, this work may aid in placing beyond a doubt the inutility of quarantine, as applied to arrivals from countries where Yellow Fever prevails.

"These resolutions were put to the vote and adopted,"

FRANCE.

Sanguineous Uterine Tumour.

Several of the later meetings of the SURGICAL SOCIETY OF PARIS have been occupied with the consideration of *Peri-Uterine Sanguineous Tumours*. M. Monod detailed a case which resembled displacement of the womb backwards, but which proved to be effusion of blood into the utero-rectal pouch. The tumour was punctured and gave issue to semi-coagulated blood. The patient died of peritonitis. M. Nelaton stated that he had met with six cases of this affection. He described the symptoms as very undecided, and not to be distinguished from those of other uterine maladies. The effusion generally appears first in the recto-vaginal cul de sac, whence it may extend into the iliac fossæ. In one of his cases simple puncture was sufficient to effect a cure, in others larger incisions were required; in two, spontaneous evacuation of blood took place by the rectum.

M. ROBERT believes that these extravasations are formed gradually, a fresh addition being made at each menstrual congestion. He also spoke of the resemblance of the tumour thus formed, to the retroverted fundus. The diagnosis is made out by the aid of the uterine sound. It is still more difficult to distinguish them from pelvic abscess, especially when the broad ligaments are implicated. In attempting the evacuation of these large collections of blood, M. Robert prefers puncture with a trocar to incision with a bistoury. He speaks of one case in which the extravasation formed a tumour reaching nearly to the umbilicus, with great exhaustion and severe expulsive pains. In this case puncture was resorted to several times.

According to M. HUGUIER these extravasations may be situated between the uterus and rectum, or in the lower part of the peritoneum. He divides them into two principal classes:—1. Those situated beneath the peritoneum in the cellular tissue, which unites the uterus and rectum, and extends on each side to the uterine appendages. 2. Those situate in one of the uterine appendages, and involving several varieties, such as—1. The pseudo-hæmatoceles which result from extra-uterine conceptions arrested in the second or third month. 2. Retention of blood in the genital cavities, or in the recto-vaginal cul-de-sac. 3. Hæmatocele arising from rupture of the ovarian bloodvessels. The

symptoms are a tumour felt in the posterior wall of the vagina, with obscure fluctuation, and displacing the uterus forwards.

Cauterization of the Neck of the Bladder for Incontinence of Urine.

M. Demeaux (*Revue Medico-Chirurgicale*, Sept., 1851,) gives several cases in which this annoying malady was speedily cured by Lallemaud's operation with the caustic bougie. Two cases were males, the third a female.

The involuntary emission of urine at night is frequently observed in infancy, but it seldom occurs after eight or ten years, and when it does so the tendency generally disappears at puberty. Numerous measures have been recommended, such as cantharides, tinctura ferri muriatis, and strychnine internally, blisters to the sacrum, &c., but as all these measures occasionally fail, M. Demeaux's proposal is well worthy of attention.

New Mode of Curing Ectropia.

This consists in causing adhesion of the lids or symblephæon, having previously liberated them by means of circular incisions; they are left united for several months, until the space above and below has quite cicatrized, when the lids are again separated. This new operation is devised by M. Mivault, and mentioned, with cases, in the *Revue Medico Chirurgicale*.

Mode of Exhibiting Balsam of Copaiba.

M. Guibourt, (*Journal de Chimie*), uses thirty parts of balsam to four of sulphuric acid, stirred together in a glass mortar. A solid mass is the result, which is readily made into pills, and covered with sugar, or silvered, according to the taste of the patient. This process affords a good test of the purity of the balsam, as, if it is adulterated with castor oil, it will not solidify.

On Amputations in Children.

M. Guersant has repeated occasions to amputate the limbs of young children in the *Hopital des Enfants Malades*. He generally adopts the flap operation, and seldom, or never, performs the circular. Chloroform is always used. He is very careful in preparing the patient for operation, and allows a liberal diet after it, which latter is the secret of his great success.

General Retrospect.

PRACTICAL MEDICINE AND PATHOLOGY.

On certain Secondary Forms of Diarrhœa.

By Dr. SANDWITH.

Dr. Sandwith considers diarrhœa, in reference to treatment, under two general secondary forms:—1. Cases in which the blood has been poisoned. 2. Cases depending on some local or constitutional irritation.

1. Instances of the first variety are observed in

diseases in which the blood has been contaminated by some poison, in which cases the diarrhoea is often salutary. Thus Mr. Lee has noticed it as a frequent symptom in his experiments on the introduction of pus or putrid fluids into the blood. He says:—

“The general result of the introduction of putrid fluids into the system, whether directly into the circulation, or by absorption, is to produce a peculiar affection, characterised by congestion, of the mucous membrane of the intestines. The evacuations that accompany this condition are evidently an effort of nature to relieve the system from vitiated fluids, &c.”

The same phenomena are noticed by Dr. Sandwith as occurring in fevers; and in these diseases, being salutary, should not be interfered with unless approaching collapse renders their suspension advisable. In the early stages of remittent and intermittent fevers, he considers it peculiarly dangerous to arrest diarrhoea by astringents, and states that he has seen, under such circumstances, the irritation transferred to the pulmonary or cerebral organs. A safer plan, in his opinion, is to obtain the alterative effects of turpentine, combined with castor oil, in small doses.

2. As examples of the second form of diarrhoea, Dr. Sandwith adduces the *diarrhoea of dentition*. Sudden suppression of this discharge is dangerous. The proper treatment is by regulation of the diet, and alteratives, unless the prostration ensuing from it calls for active interference.

In the *serous diarrhoea of the puerperal state*, in the early stage, with great thirst, hot skin, and rapid vibratory pulse, and pain on pressure, astringents or opiates are hurtful. Here general or local bleeding, salines, and diaphoretics, are the appropriate remedies.

In diarrhoea from hepatic congestion, and in that of vicarious suppressed evacuations, the same principles of treatment are adopted. In the latter, in addition, means should be adopted to restore the suppressed secretions, whether uterine or cutaneous.—*London Journal of Medicine*, January, 1852.

Diagnostic Symptoms of Phthisis.—By M. VALLEIX.

In his “*Guide des Medicin Praticien*” M. Valleix lays down the following diagnostic signs of phthisis in its two stages:—

Positive Signs of Phthisis in the Early Stage.—Dry cough, existing for a lengthened period; more or less discomfort in breathing; pains in the chest; night sweats; emaciation; dulness on percussion under one or both clavicles; weakness, or other alteration of respiratory murmur; hæmoptysis, in many cases.

Positive Signs at the End of the First Stage.—Cough more frequent; expectoration of opaque sputa; hæmoptysis; night sweats; marked emaciation; more extensive and complete dulness on percussion; blowing respiration; sub-crepitant rales; increased vocal resonance.

Positive Signs in the Advanced Stage.—Persistent cough; sputa greyish, opaque, irregular in form, and streaked with blood; increased emaciation; extended dulness; tracheal and cavernous respiration; mucous

rales; gurgling and pectoriloquy; bruit de pot fêlé, amphoric blowing, and metallic tinckling (in large excavations).—*British and Foreign Medico-Chirurgical Review*, Jan. 1852.

On the Treatment of Diabetes.—By J. HOGG, Esq.

The chief indications of treatment appear to the author to be the prevention of the elaboration of sugar in the stomach, and to restore the defective power of the digestive apparatus. This end he seeks to accomplish by the use of a medicine which will effectually destroy saccharine fermentation, and his choice fell upon the sulphuret of arsenic. To effect the conversion of this medicine into a soluble sulphuret, which would not accumulate in the system and produce dangerous consequences, he formed it by the combination of the hydro-sulphuret of ammonia with liquor arsenicalis.

One case is related as an example of the beneficial effects of this treatment, but it is not a very satisfactory one. It is true that the diabetic symptoms ceased, but the patient died of phthisis, exemplifying what is a well-known pathological fact,—viz., that toward the close of diabetes, especially where pulmonary lesions become prominent, the saccharine impregnation of the urine often disappears.

Another case is alluded to of a more promising character. The mode of administering the medicine is as follows:—℞ Liq. Arsenicalis, ʒ ij.; Ammon, Hydro-Sulph., ℥ xx.; Tinct. Hyoscyami, ʒ. ij.; Inf. Buchu., ʒ viij. Dose, ʒ ss. every four hours.—*Lancet*, January 3, 1852.

SURGERY.

On the Treatment of Aural Polypus.—By JOSEPH TOYNBEE, Esq., F.R.S.

Mr. Toynbee divides polypi of the ear into three classes:—1, the vascular polypus of the most frequent occurrence; 2, the gelatinous polypus; 3, one which is not much known,—the globular vascular polypus.

The treatment adopted by Mr. Toynbee, after repeated failure of the ordinary measures, is cauterization with the potassa cum calce. His mode of using this caustic is as follows:—The external meatus having been syringed with tepid water, so as to remove the whole of the discharge from the surface of the polypus as well as from that of the meatus, the tube and polypus should be dried by a portion of fine cotton wool attached to the end of a probe. A portion of glass tube, about an inch and a half long, should then be selected, and care ought to be taken that it is so embraced by the meatus, that it is not liable to be shifted from its position by any movement of the head of the patient. This portion of glass tube is to be introduced into the meatus, and passed inwards as far as the polypus, when, by a gentle pressure, a portion of the free extremity of the polypus is made to protrude into the interior of the tube, and is surrounded by it. Upon looking into the tube, and ascertaining that the polypus is embraced by its inner extremity, the tube is

steadied by the left hand, and with the right a portion of the potassa cum calce is passed inwards, and gently pressed against the polypus. If a pair of rectangular forceps be used, neither the hand of the surgeon nor the instrument he employs prevents the operator from seeing the polypus while he is making the application, and he can, therefore, be sure that he touches the whole of that part of the growth which is in the tube. The immediate effect of the application of the potassa cum calce upon the surface of the polypus, is to change its colour from a bright red to a livid hue, and this takes place without any pain being experienced by the patient, if the meatus has been completely guarded. After the application has been made, the patient should sit still for three or four minutes, and the tube allowed to remain as it was fixed during the operation. Upon inspecting the polypus at the end of these minutes, it will be found to have changed to a dark purple colour, to have blood oozing from it, and, instead of its former rounded extremity, it presents an uneven pulpy mass. The meatus is now to be syringed out with tepid water, when blood, mixed with the *débris* of the polypus, will come away; the surface of the polypus still remains of a dark colour, and, during several hours, a process of slow dissolution takes place in all that portion which the escharotic has reached.—*Medical Times and Gazette*, January 3rd.

Hernia Reduced "en Masse." Treatment.—By Dr. BLACKMAN.

In a pamphlet on this frequently fatal accident, Dr. Blackman advises that our first effort should be directed towards the reprotrusion of the hernial tumour. Sometimes the slightest exertion will suffice for this, in others it cannot be accomplished without the ring is widely dilated. If coughing, sneezing, jumping, and straining, do not effect the descent of the hernial tumour, the inguinal canal is to be laid open, and the sac being dragged down, the stricture is to be divided.

Mr. Luke directs that, after the neck of the sac has been divided, during the reduction of its contents, caution should be used for the prevention of that of the sac also, an accident not at all unlikely to occur, in consequence of the breaking up of its adhesions to the surrounding parts. We may easily ascertain that the contents of the sac have been liberated by passing the finger through its neck.

The author repeats the fact that after a hernial tumour has been returned by the taxis, the patient may still perish with all the symptoms of strangulation, though the sac be empty. The peristaltic action of the intestines may be prevented by the inflammation which their incarceration has produced, or they may still be strangulated by the apertures of the omentum or mesentery through which they have protruded into the hernial sac, and which still embrace them, although reduced. If the exposure of the inguinal canal discovers the empty hernial sac adhering to the spermatic cord, he says we may reasonably conclude that the patient suffers from one of the causes mentioned; and if the parts affected cannot be reached by the finger, or made to redescend by the efforts of the patient, our only resource will be to make use of the means proper to subdue peritoneal

inflammation if it exists, and to restore the action of the intestinal canal.

The exploratory operation will, the author affirms, even from the exposure of the inguinal canal alone, remove many of the obscurities of the case. If, for example, as in one of the examples which occurred to Dupuytren, the patient is unable to give an account of himself, but is labouring under all the symptoms of intestinal obstruction, if the incision of the integuments brings into view an empty hernial sac, the non-existence of the reduction *en masse* will be at once established, and our treatment must then be modified according to the other circumstances of the case. The dependence of the symptoms upon some form of internal strangulation may perhaps be established by the character of the matter vomited, as has been noticed by Dupuytren. He declares that the vomiting of mucous or bilious matter may indicate an irritation, a gastritis, or enteritis, as well as a strangulation, but if it be of a golden yellow colour, having a stercoral odour and a *matière délayée*, there need be no doubt upon the subject. We have taken it, he observes, for granted, that on the examination of the inguinal canal, if the hernial sac be found at all within it, it will be seen in front of the spermatic cord, but it will be well to bear in mind the deviations in this respect which sometimes take place, and which have been described and delineated by Camper, Scarpa, Sir Astley Cooper, Mr. Lawrence, and others. These varieties in the course of the cord and its vessels, however, are so rare, that they can hardly be expected to embarrass our proceedings.

New Operation for Stricture.—By Mr. SIMON.

Where it is of importance rapidly to relieve a distended bladder, depending upon impassable stricture, Mr. Simon has, in several instances, performed a very simple and effectual operation, which has the additional advantage of being equally adapted to cases of simple permanent stricture and those complicated with retention. Mr. Simon passes the finger of the left hand into the rectum, and feels for the prostate gland: so soon as he has well made out the position of this, he plunges a narrow bistoury into the raphe, about an inch anterior to the rectum, and carries the point of it towards the tip of the finger; the back of the knife is turned towards the finger, and thus the urethra is at once reached, posterior to the stricture. This immediately relieves the retention, and he then allows the stricture time to dilate a little, which it does when the pressure is taken off from behind, and then it can be dilated by the bougie, &c. Mr. Simon has performed this operation in several cases with success. The first case of all was that of a man who was sinking rapidly, the bladder distending, the tongue growing brown, and typhoid, great anxiety, &c., and who would have died before the ordinary operation of cutting down upon the stricture could have been executed. It was accomplished in a very short time, and was quite successful.—*Medical Gazette*, Dec. 20, 1851.

On Operations for Impassable Stricture of the Rectum.
By J. B. CURLING, Esq.

Two operations are recommended: one, the opening of the colon in the left groin; the other, opening the

bowel in the left lumbar region. Mr. Curling thus speaks of their relative merits:—"A careful consideration of the advantages and disadvantages of the two operations, leads me to give the preference to the former. I do not ground this conclusion upon the tables of Amussat and Vidal, because I do not attach much value to them. The cases of Littré's operation are not only limited in number, but in several of them the colon was not opened in the left groin, the division of the peritoneum being the only circumstance in common. Nor do the tables afford information of the period of constipation, or of the extent to which the viscera were disturbed in the operation. Callisen's operation is not only difficult of execution, but the wound is necessarily of large size, especially in stout people. But it is not so much for these reasons that I am indisposed to adopt it, as in consequence of the operation leaving the patient exposed, afterwards, to risks and annoyances, which are in a great measure avoided when the colon is opened in the groin. Thus I find, in the published account of several of these cases, that the artificial anus in the loin had a strong disposition to contract, so as to interfere with the passage of the fæces, and that repeated dilatation was necessary to secure the patency of the opening. It is also extremely difficult to adjust any apparatus to prevent the continued escape of flatus and fæces; and as the orifice is without the observation of the patient, he becomes dependent on the assistance of others. These serious inconveniences, if experienced at all, are much less so when the aperture is in the groin. The patient can attend to the part himself. The aperture does not show the same disposition to contract, and it admits of being closed by a well-adapted truss. These advantages, so important to the comfort of the patient, are by no means counter-balanced by any increased risk in opening the peritoneum. The operation is easily performed, and as no exploratory attempt is necessary to relieve the obstruction, a very small opening in the peritoneum is sufficient for the object in view. Even Callisen's operation is not entirely free from risk of peritonitis from disturbance of parts; and the magnitude of the incision probably renders the danger to life, from its performance, quite as great as that resulting from the operation in the left iliac region, carefully performed.

"The abdomen may be opened in the left iliac region by a perpendicular incision about three inches in extent, commencing two inches above Poupart's ligament, and an inch external to the epigastric artery. The fibres of the abdominal muscles being cut across, will help to keep the wound open. The peritoneum being divided, the distended colon will immediately protrude at the wound. A curved needle, armed with a silk ligature, being passed through its coats above and below to prevent its receding when emptied, the bowel may be opened for the space of an inch between the retaining ligatures."

—*Observations on Diseases of the Rectum*, p. 106.

Five Calculi Removed by Lithotomy, each containing a Field Bean as a Nucleus.

The following remarkable case is related by Dr. Mackenzie:—A labourer, aged 46, was admitted into the Edinburgh Infirmary with the usual symptoms of stone. On sounding, the presence of more than one

calculus was ascertained. The lateral operation was performed on the 13th of October, and five stones were removed. The prismatic shape and uniform size of these were remarkable; but the presence of a foreign body as a nucleus was not suspected until the stones had been dried by evaporation, when a hard substance was heard to rattle loosely within them. On making sections of these calculi, the nuclei were found to be horse-beans. The calculous incrustations consisted of the triple phosphates.

The history of this remarkable case is as follows:—About the end of March of the present year, after a carousal with two fellow-labourers, with whom he lodged in a barn attached to his master's farm, a quarrel arose, in which he was knocked down and overpowered by his two companions. From the injuries he received, and from his state of intoxication, he was rendered senseless, and, whilst in this condition, the following cruel trick was perpetrated on him by his assailants:—

He was stripped of his clothes, and a quantity of beans (the common field or horse-beans, used for feeding cattle) were thrust into his mouth and into the rectum; and lastly, several were introduced into his urethra. The manner in which these found their way into the bladder is unknown, but it is probable that several were introduced, one after another, into the orifice of the urethra, and then pushed back along the canal by the pressure of the fingers on the penis and perineum.

On the following morning he was found in a state of insensibility, with his genital organs covered with blood. His companions had made off, and have ever since escaped detection.

A number of beans were vomited, and passed *per anum* on the day following the assault, and during this and the subsequent day he suffered great pain in voiding his urine, which was mixed with blood, and contained several fragments of broken beans.

He was confined to bed for some days, but at the end of a week he had nearly recovered from his injuries, and his urinary symptoms had considerably abated in severity.

From that time forward, however, he continued to suffer more or less severely from the usual symptoms of stone in the bladder, which were well marked at the time of his admission into the hospital.—*Edinburgh Monthly Journal*, Jan. 3, 1852.

DISEASES OF WOMEN AND CHILDREN.

Case of Eclampsia Nutans or "Salaam Convulsions."—

By Dr. BIDWELL.

The subject of this case suddenly lost the power of motion at the age of three months. The bowels were at this time remarkably costive. About the same time her intelligence seemed below that of most infants of her age; but after recovering the use of her limbs nothing further was remarked till she was almost six months old. At this period she was seen to bow her head repeatedly during the day. There was no expression of pain, but apparently a momentary loss of consciousness. The feet were habitually cold.

With the exception of a few remissions, the peculiar convulsions increased in frequency and intensity, and by the time she was a year old it was evident that her

mental development was much retarded if not entirely arrested. Subsequently her bodily growth was slow. Gradually the morbid movement increased in extent; from a simple nod, it became so great that the face was not infrequently struck against the floor. This was repeated several times during the twenty-four hours. Still later epileptiform fits were added, and towards the end of her second year she was hopelessly epileptic and idiotic. The child died at the age of twenty-six months; but unfortunately no *post-mortem* is recorded.—*New York Journal of Medicine*, November 1851.

Correspondence.

ABSORPTION OF THE MAMMÆ AND TESTES UNDER THE USE OF IODINE.

To the Editors of the *Provincial Medical and Surgical Journal*.

GENTLEMEN,—In your number for January 21st is the following query from Mr. Gall, of Ripley :—"Have any instances been observed and noted of absorption of the mammæ or testes under the use of iodine?"

In answer to this I take leave to state, that I have seen numerous instances of what I consider the prolonged and excessive use of the preparations of iodine in constitutional syphilis, principally the iodides of potass and iron. The following are the cases which I recollect as most remarkable:—

A surgeon, aged 47, consulted me in the early part of this year for certain symptoms of an old venereal taint. He had taken, he informed me, ten grains of the iodide of potass twice or thrice a day, for ten years. There was no wasting of the testes. He had sarcocele, clearly venereal, with a small hydrocele on one side; the testis on the other was healthy, but there was hypertrophy of the tongue, which was tender, and covered with lobes or nodes, and fissured by deep cracks.

I have seen this condition of the tongue so frequently in persons who have taken the iodide of potass for long periods, that I must consider it a pure chronic glossitis, produced by the continued use of this salt.

A German gentleman, who had suffered from secondary syphilis for five years, and who had been treated by Ricord, Chelius, and others, was sent to me for my opinion as to the nature of the disease in his tongue. He had taken large quantities of iodide of potass for four years, "in fact (said he,) I have taken so much iodine that my perspiration turns all my linen brown." The tongue was tender, swollen, lobulated, and fissured by deep irregular cracks. The testes were of good size, and appeared perfectly healthy.

In a third case the patient had taken five grains of the iodide of potassium three times a day, for the greater part of three years.

When this patient consulted me he was emaciated and weak, and his appetite was totally gone. He at that time presented no symptoms of venereal taint, and attributed the whole of the indisposition under which he laboured to the prolonged use of the iodide. The testicles were healthy, and of full size.

A gentleman, who had suffered from a constitutional

venereal taint for thirteen years, whose disease had resisted the usual methods of treatment, or returned when they were discontinued, was sent to me from town, to try my method of treatment by "moist mercurial vapour." He had taken large quantities of the iodide of potass for long periods. The tongue presented the appearance already described; it was in places hard and lobulated, in others fissured by deep cracks. The left testis had almost entirely disappeared; it was reduced to the size of a pea. The right was of full size, and healthy. Virility was not impaired.

I have selected these four cases from amongst a mass of others, to furnish a reply to Mr. Gall's question; they are remarkable, from the large quantities of the iodide of potass which had been taken, and the length of time it had been continued. It is singular that three out of the four cases should present that peculiar condition of tongue, almost cancerous in its appearance, which I believe due to the use of the iodide. I never saw such a condition of tongue, however long a constitutional taint had been present, (and I have treated cases of twenty-nine years standing,) unless the iodide of potass had been taken for a long period. The fourth is the only case I have seen where absorption of the testis appeared directly due to the use of the above-named salt.

I am, Gentlemen,

Your most obedient Servant,

LANGSTON PARKER,

Surgeon to the Queen's Hospital, Birmingham, and Professor of Anatomy in Queen's College, &c., &c., &c.

20, Colmore Row, Birmingham.

January, 1852.

TREATMENT OF SCIATICA.

To the Editors of the *Provincial Medical and Surgical Journal*.

GENTLEMEN,—Following out the suggestion of Dr. Radclyffe Hall in his admirable papers lately published in the *Journal*, that we should endeavour to concentrate the diffused experience of the Association upon any practical point in medicine, and thus reduce, as much as possible, facts into the form of laws, I offer to the notice of the Association the following proposition:—

SCIATICA, whether connected with rheumatism or not, and not dependant upon mechanical causes, as accumulation of fæces, tumours, &c., may be cured in fourteen days by rubbing along the affected nerve, from its origin downwards, half a drachm of veratria ointment (gr. v. to oz. ss.) every night at bed-time. The friction to be performed with a horse-hair glove until severe tingling is induced.

If each member of the Association will be kind enough (and the disease is just now unusually prevalent,) to test the truth or error of my proposition, and favour me with the result, I will tabulate and insert in the *Journal* the concentrated experience of the members.

Yours obediently,

C. R. BREE.

Stowmarket, Jan. 27, 1852.

THE NEW MEDICAL BILL.

To the Editors of the Provincial Medical and Surgical Journal.

GENTLEMEN,—The draft of the proposed Medical Bill has now been in the hands of every member of the profession, and your columns will doubtless proclaim the opinions of many, favourable and unfavourable to the propositions, which must have occupied much time and thought in being brought to the maturity they have obtained. Whatever may be the fate of the measure, there is, no doubt, a debt of gratitude due from the members of the medical profession to the framers of the Bill; and I, for one, cannot express my thanks better than by stating my sincere wish that it may become the law of the land before three months have passed away. As this is the time to suggest any alterations in it, I propose to mention a few things which have occurred to me as likely to render the measure more complete, and therefore more acceptable.

SECS. 14 & 15.—In sections 14 and 15 it is proposed to substitute the payment of £10 for the larger fees which are now required by the College of Surgeons and Apothecaries' Company for licence to practise. It appears to me much more suitable to raise rather than to lower this payment; and I do not consider that the Council should have the power to grant a licence to practise unless the candidate produce a diploma from a Royal College, or from the Apothecaries' Company.

SEC. 17.—Is not twenty shillings per annum too much for a registration fee?

SEC. 18.—Should not the profession know something more about the intended "Provident Fund?"

SEC. 24.—A druggist may recover for medicines administered and supplied by him; and section 36 does not prohibit the mischievous practice of a druggist prescribing and administering medicines. Here, I think, lies the chief fault in this otherwise excellent Bill. The chemists and druggists have taken from the Licentiate of the Apothecaries' Company much of his business; and counter-practice has of late years increased to a great extent. It is for this Bill to remedy the evil, and provide a penal clause binding all chemists and druggists not to give medicines to or for any sick person, unless such medicine shall have been prescribed by a licenced practitioner; and prohibiting them from giving any medical or surgical advice, with medicine, under a penalty easily recoverable. It ought not to be sufficient that they should be unable to recover at law, but the law ought to be far more stringent than it is at present.

SEC. 26.—What is the meaning of acting as a surgeon, and acting as an apothecary? Should not the words, "For gain or profit" be added?

SEC. 32.—Who is to bear the expenses of prosecution; and in whose name are prosecutions to be made?

These few questions and remarks have been made for the purpose of endeavouring to make an addi-

tion to the usefulness of the Bill; and as I do not doubt but that you will have a multitude of counsellors, I trust you will find that there will be that for us which we do not now possess—safety.

I am, Gentlemen, your obedient Servant,

GEORGE FRED. WILLS.

Crewkerne, January 27, 1852.

Medical Intelligence.

MARYLEBONE COUNTY COURT.

Before A. AMOS, Esq.

BROWN v. BANKS.—This was an action of great importance to the medical profession, and to the public who require their services at a distance, and it being the first brought to determine what mileage should be allowed since the introduction of railways, excited much interest to the members of the medical profession in attendance. The plaintiff is a consulting-surgeon of 27, Oxford Street, and the defendant is a gentleman residing at Leighton Hall, in Nottinghamshire. The sum sought to be recovered was £39. 7s. 6d., for medical attendance upon Mrs. Haffenden, defendant's sister.

Mr. BROWN said that he was the medical attendant to defendant's family. On May the 23rd Mr. Banks called upon him, and requested that he would go *instantly* to see his sister, who was dangerously ill at Leighton Hall, Notts, a distance of 150 miles. He travelled by rail, and returned to town on the 24th. Considers the sum charged is small. The usual charge is 10s. 6d. per mile, or 15 guineas per day; and 7s. 6d. per mile for 300 miles is not a large sum. Met two medical men at Leighton Hall, and consulted with them. Mrs. Haffenden was in danger, and had been so since her marriage. The lady's complaint was of too delicate a nature to detail. The charge for post-horsing by M.D.'s was £1. 1s. per mile, but by rail the charge was 15s. 6d. per mile.

By Mr. PARRY.—Knew the family for three years. Travelled to Leighton Hall by first class. Is in practice as a consulting-surgeon. Keeps books, but has not practised as an apothecary for five years. Was obliged to have a deputy to visit his patients whilst he was absent. The deputy was not employed specially, but by the year. It was inconvenient to say how he paid his deputy.

Mr. PARRY.—I take it to be an extremely moderate sum, which will satisfy me.

Plaintiff's examination resumed—Mrs. Haffenden had, previously to my going down, written to see me. I said I would go for her for ten guineas, on condition of receiving two days' notice. I understood Mrs. Haffenden would pay me out of a small annuity she had. The husband of the lady has treated me in very discourteous terms. He has repudiated my services. Am not suing the husband. Had been to Dover, for which £33 were charged. There is no difference in the charges of consulting-surgeons or physicians.

Dr. TYLER SMITH, of 7, Upper Grosvenor Street, examined by Mr. PARRY, said he practised as a phy-

sician for the last eleven years. He knew more of the fees usual for distances among physicians than surgeons, but he believed them to be the same. Since the introduction of railways, physicians' fees had varied considerably. In the old days of posting, one guinea per mile was usual. In journeys by railway, physicians, summoned suddenly from their practices in London, now generally obtained two guineas for every three miles; others, high in the profession, considered one guinea for two miles sufficient. He had been paid at both these rates when called from London into the country. Some preferred to be paid according to the time occupied in the country, as three or five guineas per hour. Great injustice would be done to practitioners in the country if physicians took journeys into the provinces from London for low fees. The sum now charged was reasonable, considering the distance. It was below the average fee rather than otherwise. The plaintiff's solicitor asked if the witness had not been written to respecting this case before Mr. Brown had gone down to Newark. The examination of Dr. Tyler Smith was here stopped by Mr. Parry.

Mr. LANE, of 1, Grosvenor Place, consulting-surgeon, deposed to the fairness of the demand for that distance.

By Mr. PARRY.—Has been a consulting-surgeon for twenty-five years. Is related to the defendant. He is nephew to his (witness's) wife. Considers distance an important element in the matter. In a long journey, say over 200 miles, some difference is usually made.

Mr. PARRY said a gentleman like Mr. Banks did not repudiate a fair claim, and for the credit of the family he did not throw the liability upon his sister's husband. The demand was preposterous. It was at the rate of £4500 per year, leaving out Sundays, though he believed medical men did not consider the Sabbath a day of rest. The plaintiff was not in the same position as a physician, who could not for a moment have left his patients in the hands of an assistant with less than £100 a year, as Mr. Brown did. The plaintiff had not proved the loss of a patient. His books show some days he takes seven, and sometimes three, guineas per day. The calling in of medical men, as in this instance, to state their fees, was like calling in counsel to cut down lawyers' fees. (Laughter.)

The JUDGE said it was a great difficulty to determine the equitableness of medical men's fees, as the railways had so disarranged them. The defendant had, it appeared, paid twenty guineas into this court, as being what he considered ample remuneration. He had not, however, called in the same valuable opinions as the plaintiff had, to support his view. The plaintiff's witnesses considered the charge below the market price, and this evidence fully satisfied him that the claim was fair. In his own opinion he did not consider it at all unreasonable, and should therefore give a verdict for the plaintiff with full costs.—*Lancet*.

PROSECUTION BY THE APOTHECARIES' COMPANY.

At the County Court held before Mr. Losh, barrister, at North Shields, on the 23rd of January, an action was brought in the name of the Master, Wardens, and Society of the Arts and Mystery of Apothecary,

London, against Mr. Jas. Scott, surgeon, Killingworth, for the recovery of penalties of twenty pounds, in two cases, for having vended medicine, not being a licentiate of that body. It appeared Mr. Scott held a diploma from a Scotch institute, and had been located at Killingworth above a year. It is the custom in colliery districts for a medical man to contract to attend pitmen and their families for sixpence a fortnight, the sixpence being stopped off by the under viewer at the colliery upon the pay day. Mr. Scott had contracted with a number of the men at Killingworth and Gasforth collieries, and in doing so had cut out some regular practitioners. Formal proof of attendance in two cases was given. One cause was barred, by six months having elapsed since defendant attended the patient. In the second case, however, his Honour gave judgment for the full penalty of £20, and costs, to be paid at the end of two months.

COURT OF COMMON PLEAS.

WADSWORTH *v.* COLLINS.—The plaintiff is a surgeon in general practice, residing at 10, Warwick Street, Regent Street; and the defendant is an auctioneer and appraiser, living at 15, Brewer Street, Golden Square (two hundred yards from the plaintiff's residence). The action was brought for the recovery of £25, for medicines and medical attendance upon the family of the defendant, from Dec. 4th, 1850, to July, 1851. The defendant pleaded that except as to £17.10s., which was the amount charged for medicine, and which he had paid into Court, he was not indebted.

The plaintiff, Mr. Wadsworth, was examined in support of his claim, and explained the particulars of his demand, and proved from his books that the visits were made and the medicines supplied. He called several other practitioners, all of whom testified to the charges being usual and regular, and also to the custom of medical gentlemen charging both for medicine and visits.

For the defence, Mr. Sarjeant Byles said the plaintiff had no case, for he had not produced his certificate from the Society of Apothecaries. This was now handed to the Council for the defendant. It proved to be an extra-urban licence, in consequence of which the counsel contended that the plaintiff had no right to practise in the town.

Mr. Justice Talfourd overruled this objection, and stated that if a medical gentleman had his degree, it could not possibly make any difference whether it was an intra- or extra-urban licence, that being a mere pecuniary arrangement of the Apothecaries' Company, the examination for either licence being the same. It was another question whether the plaintiff might be sued for penalties for practising in London with such licence.

Mr. James, for the plaintiff, then stated that this objection had been previously decided in the case of *Young v. Greiger*; and in any case it ought to have been specially pleaded by the other side.

The counsel for the defendant then urged that it was the practice of the profession, as regulated by previous decisions, that, if medicine was charged for, visits were not.

Mr. Justice Talfourd then summed up. The jury retired for a short time, and gave a verdict for the full amount claimed, £25.—*London Daily Paper*.

INFINITESIMAL DOSES.

As a means of exhibiting the imposture involved in the so-called attenuations of homœopathic doses, "A General Practitioner" gives the following exposition:—

"The 'homœopathic globule' is composed of two ingredients, namely, sugar and a medicinal substance. Now, small as the globule is, one of the first or strongest dilution contains 99 times as much sugar as it does of medicine; for the first dilution is made by rubbing down, or triturating, in a mortar, 99 grains of sugar with one grain of medicine, so that any given quantity of this compound bears a proportion of 99 inert parts to 1 active or medicinal. The second dilution is formed by rubbing down 1 grain of the first with 99 grains more of sugar, so that any given quantity of the second dilution bears a proportion of 9999 inert parts to 1 active. The third dilution contains 999,999 inert parts to 1 active, each succeeding dilution being 100 times weaker than the preceding, and so of all the dilutions to the thirtieth, to which degree there are upwards of 70 medicinal substances in Quin's 'Pharmacopœia Homœopathica,' so directed to be prepared.

"Now, to show the quantity of sugar required to dilute one grain of medicine to the 9th degree only, we will suppose a shaft of the former three feet square, (and to begin with) half a mile long, lying before us. Having ascertained that a cubic inch of sugar weighs half an ounce, it follows, that about 3 inches, sliced from the end of this shaft, and weighing 121 lbs., will be the quantity required to dilute 1 grain of medicine to the 3rd degree. To carry on the process of dilution with the said grain to the 4th degree, will require of the above shaft of sugar 25 feet, or about 5 tons; 5th degree, 2500 feet, or 500 tons; 6th degree, 250,000 feet (50 miles), or 50,000 tons; 7th degree, 25,000,000 feet (5000 miles), or 5,000,000 tons; 8th degree, 2,500,000,000 feet (500,000 miles), or 500,000,000 tons; 9th degree, 250,000,000,000 feet (50,000,000 miles), or 50,000,000,000 tons!

"Thus, it is undeniably evident, that if the whole of a grain of medicine be diluted (as directed by Hahnemann and the homœopaths) to the 9th degree only, it will require of the above-described shaft of sugar, 50 millions of miles, the weight of which would be 50 thousand millions of tons!

"Again, if 250,000,000,000 feet (the length of the said shaft required for the 9th dilution of one grain of medicine), be multiplied by 9, it will give the number of cubic feet which it contains; and if this be divided by 30,000,000, which is about the number of cubic feet of air contained in the Crystal Palace, the quotient will be 75,000. In other words, the quantity of sugar required to dilute a single grain of medicine to the 9th degree only, would fill the Crystal Palace 75,000 times. The above calculations have been made in round numbers for the sake of convenience. The quantity of sugar required would be considerably more."

The globulists profess to use sugar of milk, not common sugar, in their attenuations; it would be an interesting speculation, supposing that one grain of medicine has ever been divided into nonillionths or decillionths, (not by any means a small dose in homœopathic pharmacy,) how many cows are required to produce the milk from which the sugar is extracted?

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on Friday, the 23rd ult. :—John Henry Bartlet, Ipswich, Suffolk; Charles Bewley, Reading, Berks; Wm. Maxwell Burman, Wath-upon-Dearne, Yorkshire; Alfred James Dale, Commercial Road; John Handford Hardy, Nelson Square, Blackfriars; Wm. A. Griffiths James, Kirkby, Lonsdale, Westmoreland; Godfrey Sandwith, Hull; George Stunt, Holland Street, Blackfriars; Edward Taylor, Staxton, Yorkshire.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, Jan. 15, 1852:—Horace Fulcher Howard, New Barkenham, Norfolk; Samuel Partridge, Darlaston, Staffordshire.

Gentlemen admitted members on Thursday, Jan. 22, 1852:—John Rerry, Leyland, Lancashire; Everitt B. Gayland, Stoke Sub-Hamdon, Somerset; H. C. Hare.

APPOINTMENTS.

At a special general meeting of the Governors of the Birmingham Dispensary, held on Wednesday last, Dr. Heslop was appointed one of the Physicians.

OBITUARY.

January 20th, at No. 1, Dalston Terrace, James Andrew Welch, Esq., surgeon, aged 54.

January 25th, at his residence, 8, Southampton Row, Marylebone, John Baptiste de Serney, Esq., M.D., aged 78.

Lately, — Williams, Esq., surgeon, Burslem. Mr. Williams was one of a party of seven who left Liverpool in September last, to form a settlement at Terra del Fuego, where, on their arrival, they were bitterly opposed by the natives, and suffered so much from absolute want of food and the vicissitudes of the weather, that all perished,

SHROPSHIRE BRANCH MEETING.

At a meeting of the Shropshire Branch of the Provincial Medical and Surgical Association, the following resolution was passed unanimously:—

"That this meeting of the Shropshire Branch of the Provincial Medical and Surgical Association, impressed with a deep conviction that it is essential to the best interests of the profession and the public that the question of Medical Reform be forthwith brought to an issue, feel much gratification in the assurance that there is a fair chance of so desirable a result in the circumstance of the Bill being brought forward in the name, and by the authority of, the Parent Association.

"The members of the Shropshire Branch beg to express their hearty concurrence in the principle of the Bill, and in the just and equitable constitution of the Medical Council. They approve most highly of a Provident Fund to which every medical man hereafter will have a legal claim, and which they regard as the best guarantee against that overwhelming affliction which is too often the lot of many who have to labour hard in a toilsome and ill-required profession.

"Finally, regarding the Draft Bill as only provisional, the members of the Shropshire Branch beg to express an earnest wish that the Council will mature the measure, and carry it on to completion, being satisfied that the profession at large will hail with gratitude the settlement of those differences and perplexities which have so long troubled its tranquillity."

P. CARTWRIGHT.

Shrewsbury, Monday, Feb. 2, 1852.

TO CORRESPONDENTS.

Communications have been received from Mr. Wilton, Dr. Chambers, Mr. Sands Cox, and Mr. West.

W. R. S. is referred to our present number for answers to his several queries. The points are not yet definitely settled. We shall be happy to receive any suggestions from him.

Agonistes is referred to No. XX., page 550, of our last volume, for information as to the conditions of the Prizes to be given for reports of Hospital Cases.

Medical Benevolent College.—Owing to the great length of the advertisement of the Second List of Subscriptions to the Medical Benevolent College, and the lateness of the time we received it, we are unable to insert it in the present number.

OPHTHALMIC SKETCHES.

SHORT LECTURES

DELIVERED TO THE

STUDENTS ATTENDING THE BIRMINGHAM EYE INFIRMARY.

By JAMES VOSE SOLOMON, M.R.C.S.,

One of the Surgeons to that Charity, lately Surgeon of the Birmingham General Dispensary.

Ophthalmic surgery an interesting and advantageous study to the practitioner. The importance of observing the deportment and expression of a patient affected with ophthalmic disease; case of a foreign body detected sixteen years after its intrusion within the eye. Mode of examining the exterior of the globe, &c. The nature of foreign bodies sometimes indicated by the occupation of the patient, &c. The treatment of foreign bodies intruded between the conjunctiva and sclerotic membranes.

GENTLEMEN,—The human eye has at all times been an interesting subject of observation and research to the scientific inquirer. The anatomist discovers in it a compendium (if the term may be allowed) of all the tissues of the body, which, with certain additional structures peculiar to this organ, form a beautifully-contrived optical instrument. The physician gladly avails himself of the study of an organ that *openly* displays to him the processes of disease and reparation, as they occur in its diverse tissues. He watches with instructive interest Nature's ways of recovering from disease, with the aids or hinderances that are afforded to her by his therapeutic measures. The occasional independence of local disease, and its capability of cure by topical applications alone, as in acute catarrhal conjunctivitis; or, what is equally true and more common, the association of local disease with morbid conditions of the blood, as in scrofulous and rheumatic ophthalmia, is here demonstrable. A number of these observations carefully made, aided by analogical reasoning, afford a key to the successful treatment of disease situated in other parts of the body, and occluded from his view by their natural coverings.

To the operating surgeon the eye presents an ample field for the exercise of judgment, delicate manipulation, and mechanical ingenuity. But, gentlemen, we must not forget that while the study of ophthalmic medicine and surgery—for they cannot well be separated—throws light upon the rational cure of other bodily diseases, it has been from those of our profession who have in theory and practice studied the latter, that ophthalmology has received the greatest advancement. To extend these observations, as might readily be done, to any greater length is, I am quite sure, unnecessary. The very fact of your assembling here to-day to gain some acquaintance with a subject as yet not included in the curriculum of the Examining Boards of this country proves to me that you fully appreciate how much may be gained by attention to this

branch of our profession. I consider the session of 1851 to be one of bright promise for Queen's College, Birmingham, when her students thus voluntarily press forward in the path of enlightenment and improvement: and I cannot doubt that those of you who are so actuated will ennoble your profession, and become instruments of honoured usefulness to your fellow-men.

If a patient present himself with "something the matter with his eyes" we must not at once lay hands upon him, draw asunder the palpebræ, and proceed to scrutinise the affected organ; but we should watch his deportment from the moment he enters our consulting room, and when he is seated, make a few general inquiries, all the time minutely noting the *position of his head*, the *expression of his countenance*, and the *condition of the palpebræ with their muscles*. Careful attention to this kind of *circumstantial* evidence is sometimes alone sufficient to indicate the nature of the disease.

When a patient comes before us with an erect head, his shoulders thrown back, and his eyes vacantly staring into space, we recognise amaurosis; but should the person be advanced in years, walk with uncertain step, his head being bent *forward*, and his eyebrows corrugated, evidently seeking a modified light, we then anticipate cataracts nearly ripe for an operation. Should it, however, be a young person—a child under the age of puberty—presenting the symptoms just related, and its chin resting on the sternum, we predicate the case to be one of protracted strumous ophthalmia, accompanied by impairment of the translucency of the cornea. You will, perhaps, be inclined to say that however abrupt and rude our examination might be of a developed case of amaurosis or cataract, the nature of the disease could not escape observation. This is true; yet you must have observed many cases which come to the Infirmary that evince, under the excitement of which manipulation is productive, far different appearances to those which truly belong to them; the membranes become highly injected, and the lachrymal gland secretes tears in abundance. To prove to you how much information may be gained by attentively remarking the conditions I have mentioned, I shall cite a case, for the details of which I am indebted to my friend Mr. Soden, an accomplished surgeon, practising in Bath.

Case 1.—"The man (says Mr. Soden) came to my house one morning with inflammation of the eye. The manner in which he held his head, the closure of the lids, epiphora, and expression of pain, all made me conclude there was 'something in the eye' before I asked him a question. On examining the eye I found considerable catarrhal inflammation, with great congestion, and a sclerotic zone round the lower half of the corneal circle. There was a small hernia of the iris a few lines from the edge of the cornea, at its lower and outer side. The protrusion was sufficient to distort the pupil to obliteration. The iris was of natural colour, and the cornea unaffected, excepting in the immediate neighbourhood of the wound, round which

there was a radiating and graduated opacity. My impression of the presence of some foreign body, from the general appearance of the eye, was so strong that I examined the bulging iris with a fine probe, and underneath it, but completely hidden, I felt a hard substance. With a pair of sharp forceps I had no difficulty in drawing it away. It proved to be a piece of iron of conical form, and really about as large as the lead that appears at the end of a finely cut pencil of moderate size (one-eighth of an inch in length). In a few days the eye was quite well. The iris retracted, but remained adherent, and the opacity of the cornea diminished to a slight scar."

History.—Sixteen years prior to the man's coming to Mr. Soden, while he was working at an anvil, a chip of red-hot steel entered the eye. He consulted a surgeon, who did not extract the foreign body, which became a constant source of annoyance to him; sometimes remaining quiet for a short time, and not unfrequently giving rise to inflammation that would not subside under many weeks. He from time to time obtained advice at several provincial and metropolitan eye infirmaries, but the nature of the case does not appear to have been recognised.

Well, gentlemen, having taken a general view of our patient, and a particular one of the points to which I have directed your attention, you continue your conversation with him; and if the eye be ever so little open, observe all you can as to the state of its cornea and adjacent membranes before you take the next step, which is, to *gently and slowly* depress the lower lid, with the forefinger placed over the inferior margin of the bony orbit, so as to expose the front of the eye, which you examine, as well as the inferior sinus and conjunctiva palpebræ. You may now, in the same quiet manner, elevate the superior lid, by placing the end of the thumb immediately beneath the eyebrow and drawing it gently upwards (the mode of doing this was here shown); and, if necessary, you will evert the superior lid in the way I am now showing you. The eye must be viewed in profile, as well as in front. By attention to these rules you will be enabled to discover the presence of a foreign body on the surface of the eye or of its appendages, which will be the subject of the present lecture. I shall reserve what I have to say on the necessary steps to be taken in the examination of the state of the cornea in purulent and scrofulous cases till we treat upon them. The same with regard to the diseases within the cavity of the eyeball.

The nature of a foreign body which has gained admission within the eyelids, the proper curtains of the eye, may be sometimes predicated by ascertaining the *occupation* of the sufferer; and by considering the season of the year, if the patient be a countryman, at which its intrusion took place. Among the latter, during the harvest, we may expect to find the seed of some plant, or the whole or part of a winged insect. Amongst *publers*, men who are engaged in the smelting of iron, a frequent accident is the intrusion of hot metal beneath

the superior lid, sometimes covering the whole front of the eye; it produces a severe burn. In these cases I would warn you not to be deterred from making a very particular examination, because some other surgeon of experience has already examined the case and removed a portion of metal. *Always* evert the lid to its full extent, and you will often find an irritating body lying in the superior conjunctival sinus. Drops of castor oil should, after its removal, be frequently applied. I shall revert to the treatment of burns upon a future occasion, contenting myself on this, with advising you on no account to prescribe a solution of nitrate of silver when the surface of the conjunctiva is excoriated, or you will *promote* a union between the free surfaces of that membrane, an accident under the best of treatment very liable to occur.

The symptoms occasioned by the intrusion of a foreign substance within the palpebræ, are those of irritation; the conjunctival and sclerotic vessels become filled with red blood, the eye waters, and the orbicular muscle is affected by spasm; the patient may complain of a sensation as of sand in the organ. As the preceding symptoms are also those of incipient catarrhal conjunctivitis, you will require to distinguish the two complaints. The history of the case, and a careful inspection of the parts, will enable you to form a correct opinion. In catarrhal ophthalmia, there is an exacerbation of the symptoms in the evening, but the sensation as of sand in the eye, is most distressing in the morning. Congestion of the iris, evinced by a diminution of its natural brightness, colour, and contractility, is an occasional accompaniment of the vascular excitement of which a foreign body is productive. After having removed the foreign body, I have invariably ordered warm fomentations, and have found a subsidence of inflammation generally within twelve hours. If symptoms of irritation continue after the removal of a foreign body, the patient complaining that he still feels something in the eye, or in the event of your being unable to discover the irritating particle, it will be proper to sweep the palpebral lining of the superior lid with the palmar point of your finger; should this fail to afford relief, as where emery has been blown upon the face of the organ, you should syringe the eye by directing a stream of tepid water within the superior palpebral sinus, in which situation the lodgement may have taken place; or you may instil castor oil within the eyelids; steruntories, by plentifully irrigating the surface of the eyeball and its appendages with tears, are sometimes a successful means of relief. In fact, any one or more of the remedies I have mentioned, may be selected at the discretion and convenience of the practitioner.

I have been occasionally called upon to remove pieces of fine wire, grass, or spicula of wood, of about one-eighth to one-third of an inch in length, lodged beneath the conjunctiva oculi, and between the plica semilunaris and the opposite margin of the cornea. They are embedded in the fine cellular structure which connects the conjunctiva with the sclerotic. You must not attempt to extract them either with or without

enlargement of the wound by which they are accompanied, but elevate the intruded substance with a pair of fine forceps, and excise its investing membrane. The conjunctiva may be freely incised and excised, without injury to the eye, of which we had abundant proof during "the squinting mania."

[To be continued.]

CASE OF ANEURISM OF THE THORACIC AORTA

BURSTING INTO THE TRACHEA, SIMULATING
CHRONIC LARYNGITIS.

By WILLIAM HENRY GOOCH, M.D., EDIN.,
PHYSICIAN TO THE KENT AND CANTERBURY HOSPITAL.

THE subjoined case was read to the East Kent and Canterbury Medical Society, and is an instructive example of aneurism of the arch of the aorta, which was not discovered during life, but produced symptoms resembling those of chronic laryngitis.

A carpenter, married, aged 44, of strumous habit, middle sized, and temperate, was admitted Sept. 20th, 1850, into the Kent and Canterbury Hospital. It appeared that about a twelvemonth previously he fell from the top of a house, and soon afterwards spit a little blood; the hæmorrhage, however, did not return. Four months afterwards he began to complain of a sense of fulness and tenderness about the upper part of the windpipe, which he attributed to a neglected cold, as he coughed a little at the time. Nothing was done for the relief of these symptoms for three months. He was then blistered, the medical attendant regarding his complaint as inflammation of the chest. No relief ensuing, he sought admission into the hospital. He was then reserved and dejected, and much wasted. He complained chiefly of a sense of obstruction behind the thyroid cartilage, with tenderness and soreness in that situation when he spoke or coughed. The cough was hoarse, and often shrill, and at the end of each fit of coughing the breathing became extremely hurried, especially at night, so that he could sleep but little. His voice was hoarse, and sometimes whispering, and he expectorated a scanty frothy mucus.

Auscultation disclosed a feeble respiratory murmur throughout the *left lung*, particularly at its apex, without rhonchus. The vocal resonance was morbidly loud, and the sound on percussion dull anteriorly and posteriorly. In the *right lung*, with the exception of a little sibilous rhonchus in the upper lobe, the sounds heard by the stethoscope, and percussion, were natural. The systole of the heart was feeble, but the sounds and rhythm were healthy. No unnatural arterial pulsation was discovered anywhere. The pulse was 84, soft, and weak. The appetite was impaired, but the tongue looked clean.

Considerable relief was afforded by cupping in the inter-scapular region, by counter-irritation on each side of the larynx, and by mercurials, with expectorants and

sedatives. Dyspnoea was alleviated, and sleep secured, by a nightly dose of chloroform. Slight œdema of the ankles now appeared, but with that exception the patient had improved and gained strength, from a nutritious diet and cod-liver oil, when soon after midnight of the 23rd of November he was seized with a sudden and very violent fit of coughing, during which an enormous quantity of blood rushed from his mouth, and he was dead in an instant. A slight aggravation of the cough had been noticed for a few days before the awful event.

Post-mortem examination on the second day after death.—The larynx and trachea showed no marks of disease. The *right lung* was emphysematous, and did not collapse when the chest was opened. The lung at its upper part was adherent to the costal pleura by long bands of lymph, both anteriorly and posteriorly. Several large red patches were scattered over the surface of the middle and lower lobe, which condition was thought to depend on the entrance of blood into the minute divisions of the air tubes, several small coagula being found in the larger bronchi. The *left lung* was universally adherent by a thick firm layer of lymph, and did not crepitate, the whole of its tissue from apex to base being in a state of grey hepatization. Three or four cretaceous deposits were found, of the size of half a grey pea, on making sections of the lung. The bronchial ramifications appeared dilated, and their lining membrane thickened, and intensely injected. The pericardium contained the usual quantity of fluid, and presented some white fibrinous patches on the surface of the right ventricle, together with adhesions between the surfaces at the base, around the great vessels. The heart was somewhat large, but its cavities and valves were natural. The aorta presented in its first portion patches of white thickening of the inner coat, and atheromatous deposits, and at more than one spot a circumscribed superficial dilatation of the coats had taken place. Immediately beyond the left subclavian artery there appeared a large opening, that would readily admit the fore-finger, which communicated with an *aneurism*, of the size of a small orange; it was situated between the aorta and trachea, and contained a small loose mass of fibrin, but had no concentric laminæ. The rings of the lower part of the trachea were bare in the posterior wall of the sac, for a space equal to the circumference of a sixpence. At this spot there were two distinct openings that passed into the trachea at its bifurcation, one of these, more properly speaking, led into the commencement of the right bronchus. The margins of these openings on the tracheal side were surrounded with tufts of lymph, adhering pretty firmly. The left recurrent nerve, after passing round the corresponding bronchus, became embedded in the wall of the aneurism. The glands between the bronchi were much enlarged, and filled with a hard cretaceous substance.

In reflecting on the case now detailed, one cannot fail to be struck with the undoubted relief afforded by the treatment to the more urgent symptoms, at the

same time that the aneurismal disease must be considered to have been advancing. To the congested and hepatized condition of the lungs diagnosticated during life, and discovered after death, we may point as satisfactorily explaining this apparent anomaly.

But the great practical lesson which the case suggests has reference to diagnosis; fresh proof is afforded by it of the obscurity which surrounds the progress of aneurisms about the commencement of the aortic arch. In the majority of instances the symptoms that result from compression of the surrounding organs, offer only equivocal evidence; it remains for a pulsating tumour, or a sudden arterial hæmorrhage, to reveal the true nature of the affection. Sometimes, indeed, the trachea, the œsophagus, or the recurrent nerve, sustain such impediments to their functions from pressure, that the diagnosis is not a matter of difficulty. On the other hand may be cited, as a striking contrast, the case recorded by Mr. Lawrence in the "Medico-Chirurgical Transactions," Vol. 6, where an aneurism of the arch of the aorta so pressed on the trachea as to ulcerate its lining membrane, and yet the patient did not experience any dyspnoea, death arose from a different cause, and the discovery of the aneurism, which was small and filled with firm laminated coagula, was quite accidental.

Laennec, when speaking of aneurism of the thoracic aorta, remarks itself:—"It cannot be known with certainty till it shows itself externally; it can hardly be suspected even when it compresses some important organ and greatly deranges its functions."

And in support of the same doctrine, the case of the late Mr. Liston may be adduced. At first, it will be remembered, his symptoms were attributed to tubercular condensation of the superior lobe of the lungs. It was thought doubtful whether the dyspnoea depended on enlargement of the bronchial glands, or on aneurism; the latter was only suspected by the distinguished physicians in attendance. This suspicion proved to be correct, for a false aneurism of the aorta was found of the size of an orange, which had burst into the trachea, and, of course, had led to the copious hæmoptysis that took place five months before death.

In the Catalogues of the Museum of the Royal College of Surgeons, and of St. Bartholomew's Hospital, three cases of aneurism pressing on the trachea are described, in two of which an opening was made into the trachea to relieve the symptoms*

* The first (No. 1665, in Catalogue College of Surgeons Museum, London,) is described as aneurism of the posterior and upper part of the arch of the aorta, attached by a narrow neck, and opening into it by an oval mouth, half an inch wide, immediately below the origin of the innominata. The sac pressed on the trachea and burst into its front part just above the bifurcation, by a small irregular opening. *Laryngotomy* had been performed (probably for symptoms pointing to the *larynx*.)

The second case (Vol. 1, series 13, No. 69, Catalogue St. Bartholomew's Hospital Museum, London,) is described as aneurism of the upper part of the arch of the aorta, involving the arteria innominata, slightly compressing the trachea. The patient was supposed to have *chronic asthma*; to relieve suffocation the trachea was opened. In the operation a large thyroïd vein was opened, and the patient died.

The third case (Vol. 1, series 13, No. 18, same Catalogue,) is that of aneurism of the arteria innominata pressing on the trachea. The patient was twenty years old, and subject to fits of dyspnoea, and in one of these she died. The canal of the trachea is slightly narrowed by the pressure of the innominata.

In the instance under consideration, the absence of all physical signs indicative of disease of the heart or its large vessels, the evidence of solidification in the left lung, the peculiar character of the voice and cough, with other symptoms, led to the inference that the chief lesion was strumous laryngitis, probably advanced to the ulcerative stage, (with pre-existent pneumonia.)

Post-mortem examination corrected the error by discovering another and an adequate cause of the affection of the throat, in the fact of the recurrent nerve being involved in the aneurismal sac; while the condition of the left lung, and the position of the aneurism, explained the paroxysms of difficult breathing.

It is right to add that a suspicion of some unusual pressure upon the recurrent nerve, like that which would be caused by enlarged bronchial glands, had been expressed by me shortly before the patient's decease.

ON THE VARIETIES OF CRANIAL PRESENTATION.

By JOSEPH GRIFFITHS SWAYNE, M.D., LOND.,

Lecturer on Obstetric Medicine at the Bristol Medical School.

THE relative frequency of the different cranial presentations has long been a *perata questio* between the professors of the obstetric art in France and Germany. The French accoucheurs have mostly taken one side of the question, and the Germans the opposite: whilst the greater number of our own countrymen have been disposed to adopt the views of the latter. As the point at issue is one which is of some importance, and which even the limited experience of individuals may tend in some degree to settle, I am induced to bring forward the particulars of a certain number of cases, which have been carefully noted for the purpose. In so doing I have availed myself only of those which have fallen under my own immediate observation, for the most part in private practice; and have refrained from making use of a considerable number which have been attended by the pupils of the Bristol Medical School, under my superintendence, because the discrimination of the varieties of cranial presentation usually requires a higher degree of the "*tactus eruditus*," than can reasonably be expected in those who are yet in *statu pupillari*.

The cases I am about to bring forward have not been selected, but have been taken as they occurred, and amount in all to 286. In classifying these according to the presentation, I shall only refer to the four kinds of cranial presentation which are commonly recognised amongst obstetric authors. In the first of these, which is the ordinary presentation of the head, the occiput of the child is turned towards the left acetabulum of the mother's pelvis; in the second, it is towards the right acetabulum; in the third, towards the right sacro-iliac synchondrosis; and in the fourth, towards the left sacro-iliac synchondrosis. The two first of these positions have been called by Velpeau and some of the French authors, the occipito-anterior positions, because in them

the occiput is placed in the anterior semi-circle of the pelvis; whilst for a similar reason the two last have been called the occipito-posterior positions. The other four positions, by means of which Baudelocque and others make out the list of eight cranial presentations, are those in which the occiput is in apposition with the symphysis pubis, the promontory of the sacrum, or the centre of one or other ilium. The existence of such positions has been denied by many accoucheurs of the greatest experience; whilst those who admit them allow that they are exceedingly rare. I have never met with a well-marked case myself, and, consequently shall make no further mention of them, as I cannot speak from experience.

With respect to the four presentations first mentioned, all authors are agreed as to the great frequency of the first, which is the ordinary presentation of the occiput towards the left acetabulum. But there is great difference of opinion as to the comparative frequency of the other three, especially amongst foreign accoucheurs. Thus, the second position, or that in which the occiput presents towards the right acetabulum, is regarded by Baudelocque, and nearly all the French authors, except Dubois, as next to the first in the order of frequency; whereas it is considered by the late Professor Naegelé and some of the German writers to be the rarest of all. Madame Boivin describes it as occurring in 19 per cent. of her cases, and Madame Lachapelle in 21 per cent; whereas Naegelé met with it only once in 1210 cases. Most of our own accoucheurs implicitly believe with Naegelé in the rarity of this presentation. On the other hand, Dr. Simpson has met with 256 cases of it in 668 cranial presentations. There is the same discrepancy of opinion as to the frequency of the third position, or that in which the forehead is towards the left acetabulum. Naegelé and Stoltz consider it to be the commonest after the first: whereas most of the French authorities consider it to be rare, and place it third in the order of frequency. Naegelé met with 359 cases in 1210, or 29 per cent., whilst Madame Boivin met with only 189 in 20,517, and Madame Lachapelle 164 in 22,243. According to Dr. Simpson it is still more rare, for he met with only one case in 668. There is not so much difference of opinion as to the fourth position, or that in which the forehead is towards the right acetabulum. Most authors consider this to be the least frequent of the two occipito-posterior positions; but this opinion is by no means universal, for Dr. Simpson met with 76 cases of this position, and only one of the third in a total of 668 cases. And Dr. Miller, an American accoucheur, who has lately written on the subject, also considers it to be much more frequent than the third.

The discrepancies pointed out are so striking, that at first sight they might lead to the belief that obstetrical statistics may be made to prove anything, but upon examination it will be found that these differences are more apparent than real. Thus Naegelé considers that nearly all the presentations of the head in the second position were originally, at an early stage of the labour, presentations in the third position, but that as the

labour progressed a change in position was effected by the natural efforts, the head rotating so as to bring the occiput round from the right sacro-iliac synchondrosis behind to the right acetabulum in front, which he believes to be the natural termination of presentations in the third position; and he thinks that from this change having been overlooked, the second position came to be considered so frequent by various authors, because what were really examples of the third position were set down as belonging to the second. His doctrines have been generally adopted in this country; but in France, where perhaps greater attention has been paid to the mechanism of parturition, they have met with some opposition. I shall endeavour, as much as possible, to test these conflicting views, by the cases which I shall bring forward. I need not dwell upon those in which the head presented in the first position, as they only confirm what has been universally observed as to the great frequency of that position. In 247 cases out of 286, or nearly 7-8ths of the whole number, the head presented in that way. I find that the second position occurred in 28 cases out of the 286. I am thus led, from my own experience, to coincide with most of the French authors as to the much greater frequency of the second than of the third and fourth presentations.

There is every reason, *a priori*, for supposing that the second presentation, which is in every way the most similar to the first, should be next to it in frequency; and there is every reason against the probability of its being, as Naegelé considers, the most rare. However, as facts are the only legitimate arguments in discussing such a question, I shall adduce one or two cases in which there could not be the slightest doubt that this presentation was the original one. According to Naegelé, the turn which is described by him as changing the third into the second position, is not effected until the head is fully engaged in the pelvis,—until (to use his words) “it experiences the resistance which the inferior part of the pelvic cavity opposes to it.” But in two of my own cases there could not be the slightest doubt that the head was in the second position when above the brim. In one of these (No. 116.), it was necessary to perform craniotomy, on account of pelvic deformity, which prevented the head from entering the cavity of the pelvis. The head was drawn through the pelvis, and delivered in the position in which it presented,—viz., with the occiput towards the right acetabulum. In another, (No. 272.), which happened lately, the head remained so high above the brim, even when the os uteri was fully dilated, as to be out of reach by an ordinary examination; the only part to be felt was one of the hands. Expecting an arm presentation, I introduced my hand into the vagina, for the purpose of turning, if necessary, and, in so doing, ruptured the membranes. I was then able to feel the head high above the pubes in the second position, in which position it descended into the pelvis after the hand had been pushed up, and remained until it was expelled. These instances alone, although but 2 out of 286, show a greater per centage of the second position than the cases

of Naegelé, who only records 1 in 1210. But in by far the greater number of the 28 cases which I have noted, I examined minutely at an early stage of the labour, when the head was high, and before the membranes were ruptured, without in any instance detecting that this position was the result of a change from the third.

My own experience with regard to the relative frequency of the third and fourth, or occipito-posterior positions does not agree with the statistics which are usually given. The third position is generally considered to be much the most frequent; but in my own cases there were only three instances of this, and eight of the fourth. This result, however, is not singular; as in Dr. Simpson's cases the difference between the two is still greater. Out of 668 cases he met with 76 of the fourth and only one of the third position. Dr. Millar, the Obstetric Professor in the University of Louisville, U.S., (whose work has lately been reviewed in the *British and Foreign Medico-Chirurgical Review*,) has met with the same result; for he remarks:—"I find by reference to my note-book that the fourth position has occurred in my notes oftener than the third, but both together less frequently than the second."

The third position, as I remarked before, has been considered by Naegelé, and also by Rigby, and other English writers, to be much more frequent than the second; and the cause which they allege for the reputed frequency of the second is, that in nearly all the cases of the second position the head originally presented in the third position, but that this circumstance was not noticed by those in attendance. From the reason which they assign one would be led to believe that the diagnosis of the third and fourth positions was a difficult matter at the commencement of labour; but this does not accord at all with my own experience. I have in general had no difficulty in distinguishing these presentations, before the membranes are ruptured, and even before the os uteri is dilated, by noticing a peculiarity in the shape and position of the os uteri, which, as far as I know, is not described in any book on midwifery. The peculiarity I allude to consists in a depression of the posterior lip of the os uteri, and an elevation of the anterior lip, dependent on the position of the child's head. In ordinary labour the child's head is, at the commencement of the labour, flexed upon its body; but during its progress the head becomes still more flexed by the chin approaching still nearer to the sternum. The result of this is, that the posterior half of the child's head is much lower than the anterior. Consequently, in the occipito-anterior presentations, the occiput being in front presses upon the anterior lip of the os uteri, and depresses it much below the level of the posterior lip. But in occipito-posterior presentations the reverse takes place; the occiput being behind depresses the posterior below the anterior lip. Hence the shape and position of the os, on making a vaginal examination, appear to be very different from that which we ordinarily find. In ordinary cases the finger passes but a slight distance into the angle, or cul de sac, formed by the junction of the vagina and

the anterior lip of the os. (See *fig. 1.*) But in the occipito-posterior positions the finger passes high up behind the pubes into the cul de sac just mentioned, which in this case forms an acute angle, as in the first it formed an obtuse angle. (See *fig. 2.*) At the same time

Fig. 1.

Fig. II.

the posterior lip, and even the entire os, is unusually low in the pelvis. From noting this circumstance I have been able to detect these presentations at an early period of the labour, and have found, as a general rule, that the head does not make the turn which Naegelé and others describe as the ordinary course of events. That it does so sometimes is, nevertheless, quite certain. In one of my eight cases of the fourth position it was very evident. In this case, as soon as the membranes were ruptured the anterior fontanelle was felt just behind the right branch of the pubes, and the right ear behind and a little to the left of the symphysis. Afterwards, as the head descended, the ear could be distinctly felt during each pain to recede from this position and come round to the right side of the symphysis, and pass backwards almost out of reach, until at last the head was expelled with the occiput towards the left thyroid foramen. Immediately upon its expulsion it regained

its former position, with the forehead in front, and looking towards the right acetabulum.

A short time ago I witnessed a similar change of position in a rather difficult case of labour which was attended by one of my pupils, and in which the forehead was originally towards the right acetabulum. But in all the other cases of the third and fourth position, amounting in all to ten, no such turn took place, but the forehead of the child continued throughout the labour in the anterior semicircle of the pelvis. But yet in all these delivery was easily effected by the natural powers, notwithstanding that the head was placed in what is generally considered an unfavourable position. So unfavourable an opinion had some of the older writers respecting the third and fourth positions that some of them considered delivery impossible whilst the head was so placed. Levret, Capuron, and Baudelocque maintained that the forceps was always required to finish such labour, unless either the child was unusually small or the pelvis unusually large. Nor are these views peculiar to the older writers. Blundell, who was generally so averse to meddlesome midwifery, nevertheless thought that the assistance of art was necessary in these cases. 'The necessity of interference was still more strongly insisted on by Dr. J. Clark, of Dublin, and also by Dewees, who went so far as to observe, that a man is "incompetent to practise midwifery in its best manner who cannot detect and change this malposition of the head, and thus abridge by several hours the misery and pain of his patient." Such opinions, however, were not universal even amongst the older accoucheurs; for Mauriceau, Smellie, and Denman, relate cases in which the labours terminated favourably by the natural efforts when the head was in this position. Amongst modern authorities, Dugés and Velpeau give instances in which unusually large children were expelled in this manner. Notwithstanding, in most works on midwifery at the present time, these presentations are classed amongst the malpositions of the child as causes of difficult labour, and it is recommended that the position of the child's head should be altered, if possible. My own experience by no means confirms this view, as in all the cases I have noted, the labour was very little, if at all, more tedious than in an ordinary presentation, although I allowed the forehead to continue in the anterior semicircle. In one of these (252) it was necessary to deliver with the forceps, on account of convulsions, but not because the labour was protracted.

I am led from this to conclude, that the difficulties which are said to attend such positions are more theoretical than practical, and that many persons have been led to believe in them, from making comparisons of dried pelvis and crania, and measuring the several axes and diameters, without making allowance for the very great alteration which may take place in the shape of a child's head during labour, and by means of which it becomes moulded to the canal which it has to traverse. Thus it has been stated, that in consequence of its shape being more

square, the forehead does not adapt itself so well as the occiput to the arch of the pubis, as the head clears the outlet of the pelvis; without considering how materially that shape may be altered by the overlapping of the frontal bones at their suture. It has been likewise stated, that at the moment of expulsion the perineum is put much more on the stretch, and is in more danger of rupture, because the occipito-frontal diameter of the child's head (which in then occipito-anterior presentation, is in relation with the antero-posterior diameter of the pelvic outlet,) is much longer than the trachelobregmatic which is in apposition with it in ordinary cases. Here again no account is taken of the great capability which the occipito-frontal diameter has of being lessened by the overlapping of the parietal and frontal bones at the coronal suture. In fact, in all these instances of occipito-posterior presentations, I have noticed that this shortening actually takes place to a great extent, so that the head is at first so much altered in shape as to be nearly round; whereas in the occipito-anterior presentations the head becomes materially lengthened, especially when the labour is at all protracted. In the 11 cases I have noted of occipito-posterior positions, the perineum did not receive the slightest injury, nor did it seem to be more on the stretch than usual. From these observations I am led to conclude, that under ordinary circumstances the occipito-posterior presentations require no artificial assistance; and that, as a general rule, the powers of nature are sufficient to accomplish delivery safely in any cases of vertex presentation.

ENORMOUS ACCUMULATION OF FLUID IN AN OVARIAN CYST.

By H. COOPER, Esq., M.D., LOND., HULL.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—The following case occurred in the practice of my friend, Mr. Denton, of Hornsea, near this place, and was seen by me occasionally in consultation. At his request I send you the following notes, which may prove of interest, as showing the enormous accumulation which may take place gradually in the proximity of important organs, without producing any injurious effects, except those of mechanical pressure; and the facility and safety with which these large amounts may be withdrawn by tapping, with proper precautions.

Ann Russell, aged 54, unmarried, of spare habit, very active and energetic, ten years ago, while papering a room, overstretched herself, and was immediately conscious of some internal injury. Shortly afterwards she felt a fullness on the right side, which, without any interference with her general health, and with only mechanical inconvenience, has gone on increasing up to the present date, Nov. 28, 1851. Her condition is now as follows:—The abdominal distension is extreme;

the girth round the umbilicus is four feet eleven inches, and the enlargement being nearly globular gives the same measurement in every direction; the skin is tense and bright, and being stretched to the utmost, the slightest touch on one side of the abdomen is transmitted to the other with singular distinctness; veins the size of the little finger traverse the abdominal tumour, and there is great eversion of the cartilage of the ribs; excessive oedema in the lower extremities, the skin of which has given way; breathlessness on exertion, orthopnoea, and almost total suppression of urine, without albuminuria, are also present. She has frequent attacks of syncope, with sense of approaching suffocation.

Mr. Denton took this afternoon, with a large-sized trocar, *eighty-three imperial pints* of a dark turbid fluid at one tapping. Faintness frequently obliged us to arrest the flow, and to give stimulants; and great attention was required to the bandages, particularly an extra one compressing the hypochondrium, from which she experienced the greatest relief. The fluid was not of high specific gravity, and not at all gluey, though of a dark chocolate colour, as if coloured by decomposed blood.

After the operation the abdominal parietes subsided in huge folds, giving to the hand the impression of a cyst very much thickened, but not painful when grasped.

Referring to the records of similar cases within my reach, I find only one in which an equal quantity of fluid was taken at one operation; and from the date of the communication I presume the old measurement, and not the imperial, would be employed. In the few other cases reported of anything approaching this quantity being removed, it has been done at severalappings, and will, therefore, have accumulated in the intervals.

I learn that the patient has done well up to the date of this letter; and that there is no very distinct evidence, as yet, of reaccumulation of fluid.

I remain, Sir, your obedient Servant,

HENRY COOPER.

Hull, December 30, 1851.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CASES

Reported under the Terms proposed by the Association.

By SCRUTATOR.

Lupus.

SARAH REEVES, aged 13, admitted under the care of Mr. Knowles, March 13th, 1850. As long back as three years before the date of admission this patient began to be troubled with a sensation of itching on the

inner side of the left ala nasi. In a short time an eruption, which appears to have been of an eczematous character, appeared, commencing from that part, and passing thence gradually over the greater part of the left cheek and some portion of the right, the child's general health at the same time continuing good. Numerous applications were made use of, both with and without medical authority, but in spite of these means the face continued bad, and the alæ of the nose were evidently being destroyed by the insidious disintegration or "eating away" of the disease, as the mother not unaptly termed it.

Upon admission the same state was observed, a considerable portion of the left ala nasi being lost. The diseased part presented appearances of two kinds, either red shining integument, from which a transparent discharge was constantly oozing, in minute drops, or concretions of the same nature being the characteristics. Appetite reported good, and all the functions regular. Menstruation not yet established. The light hair, the transparent complexion, and pearly conjunctiva, showed her to be of an eminently scrofulous diathesis, and on inquiry it was found that she inherited the taint from her father. Hab. Pil. Hydrarg. Chlor. Comp. j., omni nocte.—R. Potass. Iodid., scr. j.; Decoct. Sarsæ. Comp., oss. Sumat. oz. j. ter die.—R. Calom., dr. j.; Ung. Picis. Nig., oz. j. Misce et ap. bis die part. affect.

20th.—Continue medicine.

28th.—No change. Continue medicine.

April 15th.—No change. Continue medicine.

20th.—There being still little change the medicines were altered, and she took the preparation known as Donovan's solution, as in the following prescription:—R. Sol. Don., dr. j.; Decoct. Sarsæ. Comp., oss. Sumat. oz. j. ter die.—Ap. Ung. Hydrarg. Nit. Oxid. bis die.

May 1st.—Remains much as before. Continue medicine.

9th.—The face looks dryer, and is, if anything, better. Continue medicine.

25th.—Seems much about the same. Continue medicine. Ad. Mist. dr. j. Sol. Donovan.

June 1st.—Improved. Hab. dr. ij. vice dr. ij. Sol. Donovan in mist.

21st.—About the same. Continue medicine.

29th.—She now left the hospital evidently benefitted by the treatment, the face looking less red and dryer. She continued her medicines as an out-patient, and attended during the month of July and part of August, still going on with the same medicines and application. She had then become much better, and discontinued attendance until the summer of 1851, when she again made her appearance as an out-patient for a short time, and was again benefitted by arsenic, taken in the form of Fowler's solution. From some domestic circumstances, however, she was unable to continue as a patient, and we saw no more of her until November 14th, 1851, when she was again admitted as an in-patient.

On admission the girl was observed to be much grown, and menstruation had been established, without

any attendant suffering; she still, however, retained the scrofulous aspect, and her mind seemed more affected by the disfigurement than it had heretofore been. The disease remained somewhat in the same state, but appeared more inclined to attack the deeper structures, and some portion of the upper lip was also now lost; there was, likewise, more discharge, and more resembling pus. All the functions natural. She now had ten grains of pitch three times daily, and applied poultices to the face, to bring away the concreted discharge. This being effected, an ointment of the sulphuret of potassium was applied for some time, but without any amendment; the pitch dose was then increased to fifteen, and subsequently to twenty grains, and an ointment, composed of one ounce of lard, and fifteen grains of ioduret of sulphur used. The ointment was afterwards increased to double the strength, but failed in producing any decided result.

In the month of December she had the Ol. Aselli in large doses, and took that until the beginning of January, 1852, when she again left the hospital for change of air, more benefitted by the latter medicine than by an prior treatment. She has not returned to the hospital up to the present time, February, 1852.

Upon the patient's first admission into the hospital it was easy to diagnose a case of lupus of a mild character, and also to prognosticate that difficulty would probably be found in devising any means of relief from the disfigurement, both of which points were touched upon by Mr. Knowles in some remarks made to the class at that time. Lupus is essentially a disease which belongs to the tubercular class; and most observers, among whom Mons. Biet is prominent, distinguish three varieties of the complaint:—1st, lupus in which the ulcerative process destroys principally in depth; 2nd, that in which the destruction and cicatrization do not produce any open ulceration, but are accompanied by hypertrophy of the skin*; 3rd, lupus which spreads chiefly superficially. Others, however, make but two divisions of the disease:—the lupus exedens, or noli me tangere; and the herpes, or lupus non exedens. It seems, however, that there are many ulcerations having many of the characters of lupus, which cannot be definitely classed under either of these divisions, and of such a kind seems to be the case reported. It most agrees with that form described by Biet as superficial lupus, and yet it steadily went on from month to month, and from year to year, destroying the nose and lip of the patient. From consideration of this and other cases, it seems that all kinds of lupus might be classed under three heads—viz., that affecting the deep parts, that affecting the cutis vera, and that affecting the cuticle. In the case in point the disease seemed to confine itself to the true skin. A division of this kind is not merely of a scientific nature, but has practical bearings which are of great importance as regards the treatment to be enforced, should the disease attack the deeper parts. No heroic measures, as the arsenical

paste, &c., can with safety be adopted; but, on the other hand, should the disease be diagnosed as superficial, there is no reason why such an application should not be made use of, and the patient obtain the benefit consequent on the destruction of the diseased parts.

The case reported well exemplifies the obstinacy of the disease; medicines and applications, although persevered with to a very great extent, having but little control over it, although it must be confessed some improvement was occasionally manifested. The frequency with which the complaint is met with, combined with the scrofulous habit, points to its constitutional origin, and the good which resulted from the use of the cod-liver oil bears out such remark. In the *Lancet* of June 14th, 1851, some cases are spoken of where very great benefit was produced by the use of the same agent. No doubt the good effect is attributable to the iodine present, which substance has also been used as an external application, and is recommended as such by Dr. Houghton, in the "Cyclopaedia of Practical Medicine." Almost everything has at one time or other been used in this disease. Biet used ioduret of sulphur, which in this case did no good. Bateman recommends chloride of barytes formerly, though efficacious in all scrofulous affections. Sir Astley Cooper used an ointment of sulphur and arsenic; and Dupuytren one of calomel and arsenic. Dr. Ure recommends the chloride of zinc. And the nitric acid is said to have been used with success by Cloquet. Blistering, nitrate of silver, potassa fusa, and every caustic application, have had their advocates, while others have extolled such remedies as the galium aparine, the anthemis nobilis, the mountain flax, and other remedies of reputed efficacy in cleansing and purifying the blood of peccant fluids; or, in the language of the village doctress, from "foul whomurs." When it is determined to use any caustic application, with the view of the destruction of the part, the rule laid down by Cooper should be adhered to,—viz., not to destroy more than the extent of a shilling at one time; for, says this authority, "the paste (arsenic) requires particular caution, less the patient be poisoned by it; and, moreover, it is liable to bring on erysipelas of the face." Should, however, it be determined to apply such a remedy, it should be done effectually; and if there be any return of the ulcerative action, the remedy should be applied again.* This mode of treatment, therefore, is more applicable to lupus in its earlier stages, before it spreads to such an extent as to render the application dangerous.

Injuries of the Knee-Joint.

EMMA ROBINSON, aged 14, was admitted into the Queen's Hospital, August, 1851, under the care of Mr. Knowles, having the day before fallen down and hurt her knee. On examination, that part was found to be immensely swollen, much inflamed, and, of course, exquisitely tender, when touched or put to the slightest motion. There was a wound on a level with

* Probably analogous to lipoma.

* See Dr. Ure on Lupus. *Medical Gazette*, Vol. xviii.—Walshe. Op. Cit. p. 548.

and internal to the patella; and upon using the probe to ascertain if a dark-looking substance, obscurely visible just within the wound, was a foreign body, it struck against something hard, which being laid hold of by a small pair of forceps, was with difficulty extracted, and proved to be a nail an inch and a half in length, with a small head, such as is used for nailing down flooring. A considerable degree of force was requisite to extract the nail, and this was followed by a flow of synovial fluid, evidencing that the nail had pierced its secreting membrane, and, therefore, opened the cavity of the joint. There was also considerable constitutional disturbance present; the pulse counting 110, the skin hot, and general restlessness and irritability. The limb was kept perfectly quiet, by means of a gutta percha splint underneath, and warm medicated fomentations assiduously applied, while she had five grains of calomel immediately, and a black draught in four hours afterwards.

The next day the limb was found to be still much swollen; she had also had rigors, and complained much of throbbing in the neighbourhood of the joint, but there was no flowing away of synovial fluid. The bowels had been well moved, but the pulse remained as high as 110. Twelve leeches were now applied to the joint, and one drachm of magnesiæ sulphas and the eighth of a grain of tartar emetic ordered every four hours. The next day an abscess was opened, which appeared to have formed external to the joint on the inner side of the patella, and a large quantity of pus was evacuated with great relief to the patient.

From this date she went on well, there being no more flow of synovia, or other accession of inflammatory action. The wounds healed in the course of a month; and on the patient's discharge all the motions of the joint were perfectly performed.

ANNE HILTON was admitted June 18th, under Mr. Sands Cox, having, while engaged in bed-making that morning, ran a pin into the knee-joint. On examination, a portion of the pin was easily discernible just beneath the integument; but the pin had become bent, and the head had passed inwards, and could be felt pressing against the integument some little distance from the small wound which had been made. A slight incision was, therefore, necessary to enlarge the opening, and after some trouble, owing to the bent state of the pin, it was extracted through the wound. From the large size of the pin and the direction taken, it must have entered the joint; but the wound being small and oblique, there was no escape of synovial fluid. The patient was put to bed, the leg secured from motion, and the wound closed with collodion. She never had any bad symptom, and was discharged free of uneasiness in a few days.

Wounds implicating joints, and especially the knee, are always regarded in a more serious light than those of most other parts, followed as they so frequently are by a great amount of synovial inflammation and constitutional disturbance, so much so as often to render it

a matter of great uncertainty, not only whether the motion of the joint will ever be recovered, but also whether the patient will survive. In such cases, therefore, the propriety of immediate amputation is frequently mooted, and the opinions of surgeons are much divided on this important point. Great praise is due to the talented author of "The Mirror," who lately brought forward several cases bearing on this point, showing that injuries which, *primâ facie*, would seem to require amputation, have been recovered from, thus removing any doubt as to the propriety of attempting to save the limb, even in very bad cases.

In the first case reported in this paper the writer considers that the formation of the secondary abscess probably saved the limb, and perhaps also the patient. The abscess seems to have closed the wound of the synovial membrane, and prevented inflammation of that texture; had not this happened it is more than probable that suppuration of the membrane would have resulted, from which condition there are but few recoveries. A case of this kind, terminating favourably, is, however, given in Mr. Solly's "Lectures on Injuries of the Knee-joint," *Lancet*, January 17th, 1852.

The treatment of these cases must be thoroughly antiphlogistic, and perfect quietude of the limb must be enforced; a splint beneath answers this purpose best, leaving the anterior and lateral regions free, for the application of leeches, fomentations, &c. Calomel also should not be forgotten, if the interior of the joint is in danger; and the patient may, and should, be kept under its influence for some time, if such be the case. That the knee-joint may be opened, and no bad consequences result, we have abundant evidence; and it is of this fact that the surgeon takes advantage, and receives encouragement when using the knife for the removal of loose cartilages, &c., from its interior.

Lithotomy.

JOHN GIBSON, aged 6, admitted December 3rd, 1851. His mother states he has been ill about two years, labouring under symptoms resembling those now present, but not so severe. He is now much emaciated, and countenance is pale. The prepuce is elongated, and he is constantly pulling it. He has also pain referred to the perinæal region, worse at night. The urine dribbles away, is acid, but presents nothing remarkable when examined with the microscope. Appetite bad; bowels purged; tongue tolerably clean. A sound detected with ease the presence of a stone.

December 6th.—An enema was administered with castor oil last night, and this morning the lateral operation was performed by Mr. Sands Cox. There was no difficulty in the operation, and a calculus was extracted in rather less than a minute, weighing about five drachms. Chloroform was used previous to the operation, the boy being narcotised in the ward, and conveyed thence to the operating theatre.

Vespere.—Urine has passed by the wound; some slight abdominal tenderness. Warm fomentations to be applied.

7th.—Slept well; bowels not moved; has no pain;

urine passes freely. Ol. Ricini, dr. ij. statim. Continue fomentations.

9th.—Going on well.

16th.—The urine yesterday began to pass by the urethra; there has been no bad symptom; wound is granulating; sleeps well; seems much improved generally.

January 3rd.—Discharged well. Wound quite healed.

There was not either in the symptoms, operation, or after-treatment of this case, anything extraordinary or calling for observation. The patient made a quick recovery, but what renders the case remarkable is, that the brother and father of the lad were both operated on for stone, evidently pointing to the fact that a peculiar constitutional state, obnoxious to this disease, may be transmitted from the parent to the children. Another fact worthy of notice regarding this case is, that the child came from a quarter where stone in the bladder is a very prevalent disease,—viz., the neighbourhood of Dudley. The calculus was of an oval shape, and weighed about five drachms; its exterior was of a dark colour, friable, and laminated, probably consisting of urate of ammonia. The internal layer was of a harder description, and lighter in colour, but was not chemically examined.

Provincial Medical & Surgical Journal.

WEDNESDAY, FEBRUARY 18, 1852.

ALTHOUGH the Draft "Bill for providing Uniformity of Medical Education" has met with unexampled support in the provinces, yet its provisions seem so liable to misconstruction that we shall be pardoned for once more making allusion to them.

It appears to us that most of the objections urged against it are utterly untenable; as, for instance,—“that it will annihilate the College of Surgeons.” This, is the reverse of the effect likely to be produced, for its tendency will be, not to destroy, but simply to make the College of Surgeons what its supporters maintain that it ought to be—a College of pure surgery.

At present each member of the profession who practises generally all the branches of his art, attaches great value to the diploma of the College of Surgeons, and hides in the secret recesses of his *écritoire* the licence of the Apothecaries' Company. Now, why is this? Simply because the one is considered to be a proof that he was, as a student, *anxious to do all in his power* to test his capabilities by an examina-

tion not absolutely imperative; whilst the latter is merely obtained in compliance with the law of the land, and is *necessary* before he can practise that part of his profession which, however we may disguise the fact, is felt to be a degradation by all.

Such is undoubtedly the present estimate of the respective testimonials of the College of Surgeons and the Apothecaries' Company. Now, we confess we are at a loss to know why the Licentiate, under the new Bill, should be more likely to rest contented with his licence than the present Licentiate of the Apothecaries' Company. For *in future* no one would be allowed to call himself by the only name which the public appreciate, viz.,—“a Surgeon,” without going to the College of Surgeons for their permission; and we are quite sure that that permission will only be granted on such terms as will prevent the annihilation of the College for want of funds. The College of Surgeons has obtained such a hold of the public, as well as the profession, that its diploma will always be necessary whenever there is any amount of competition; and this estimation is not in consequence of the stringency of the examination, but because its diplomas have been signed by such men as Sir A. COOPER, ABERNETHY, BRODIE, GUTHRIE, LAURENCE, WHITE, and a long list of celebrities, who have each figured in their day at the head of the profession in London. The fact is, that so long as such names as these grace the list of Examiners, so long will their signatures be sought for, and paraded on every occasion.

We think, therefore, that the effect of the Bill will be simply to substitute for the licence of the Apothecaries' Company a licence granted by a Board of Examiners, consisting of gentlemen selected by a competent Medical Council, and in order to guarantee the propriety of this selection, the Medical Council is to be appointed by the existing institutions, so soon as they are remodelled by new Charters on the basis of the representative system. The only blot, in our estimation, in this scheme of appointment, consists in the retention of the Apothecaries' Company as an elective body, after it shall have ceased to exist, except as a trading corporation. We are inclined to think that it would be much better to place the power of selection of those members of the Council who are to consist of those engaged in general practice, in the hands of the Government.

than to leave it with the Apothecaries' Company. Between these two courses there is clearly no choice; a sufficient number to represent the "general practitioner," as he is now called, must be chosen, and there seems to be no body which can make that choice but the Apothecaries' Company. That Company, however, is a self-elected one, and can only in future, if this Bill passes into a law, be held together for the purposes of trade; it will, therefore, be scarcely desirable to allow such a body to exercise so important a trust, and we must, if such be the general opinion, fall back upon the other horn of the dilemma, and throw ourselves upon the tender mercies of the Secretary of State.

There are several other suggestions for alteration which have been made at the various meetings, published in another part of this journal; some of these will at once be appreciated as improvements, while others will, we think, deserve a different fate. It will be for the Committee to decide upon these different points, and we have great pleasure in announcing that it will meet in London for that purpose on the 25th inst., and that Sir G. GREY has acceded to their request to be allowed to express to him their opinions on the subject, and will receive a deputation on the 26th. In the meantime we hope to receive any further suggestions, and also to obtain the views of the various Colleges on the Bill.

Proceedings of Societies.

SHROPSHIRE BRANCH.

A MEETING of the SHROPSHIRE BRANCH of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION, was held at the Raven and Bell, Shrewsbury, on Monday, 2nd inst., for the purpose of taking the opinion of the members on the Draft Bill.

Mr. THURSFIELD took the chair at half-past one o'clock.

At the suggestion of Dr. JOHNSON the several clauses of the Bill were read over by Mr. PIDDUCK with the exception of 1, 12, and 31. He also read the schedules referred to in clause 13.

It was agreed that the clauses be discussed *seriatim*, and, as the first and second were merely of a technical character, they proceeded to discuss clause 3.

Mr. BROOKES said, before they entered on the discussion of the several clauses contained in the bill, he might be allowed to make a few observations. He thought it would not be amiss for them to inquire why

it was that all the measures which had been brought forward from time to time had failed to give satisfaction. He would answer for one or other of the following reasons:—Either because they had tended to lower the *status* of the surgeon or general practitioner, or because they had not been framed on a representative principle, or because they had interfered with the interests, or invaded the rights, directly or indirectly, of the existing medical institutions. By the two first of Sir James Graham's medical bills, it was proposed that the surgeon or general practitioner should practise under the denomination of a licentiate in medicine, surgery, and midwifery, after an examination by the Colleges of Physicians and Surgeons, and the Apothecaries' Company. But the licentiate so examined would have belonged to an inferior caste, possessing no corporate privileges in any of the medical institutions in the country, and consequently no control over the qualifications and examinations of his own class. The two last of Sir James Graham's bills, in 1845, proposed the institution of a college of general practitioners. According to the first of these bills the preliminary examinations were to be conducted by a joint board, consisting of six physicians and six surgeons, after which the candidate was allowed to offer himself for further examination by the examiners of the college to which he desired to belong. According to the last bill,—viz., that of July, 1845, the candidate was required to present himself for examination, first before the College of General Practitioners, and afterwards for his licence to practise, before the joint Board of Physicians and Surgeons. These bills were objected to, as they created an inferior grade unconnected by membership with the College of Surgeons; they interfered also with the interests of the College of Surgeons, inasmuch as they did not reserve to that body the sole right in England to examine in surgery. The same objections had been urged against the measure of medical reform propounded by the National Association and National Institute,—namely, their tendency to degrade the surgeon or general practitioner, and their invasion of the interests or privileges of the Royal College of Surgeons. He now came to the last attempt at medical legislation,—namely, the "Draft Bill to Secure Uniformity of Medical Education and Qualification," and wished he could perceive in it any advantages over those of Sir James Graham's and the National Association, or any stronger claim to their support. It attacked indirectly the privileges of the College of Surgeons, created an inferior grade of mere licentiates in medicine, surgery, and midwifery, possessing no electoral privileges in any medical or surgical college whatever, and abolished the necessity of passing an examination even as a member of the College of Surgeons, without which, however, no one hereafter could assume the title of surgeon. It was easy, they would say, to criticise and condemn, but would they be able to frame any measure free from the foregoing defects. He felt convinced they could. In conclusion, he urged them not to give a hasty assent to any measure which was not calculated to improve the *status* of the

general practitioner, emanate from what quarter it may. They had met there that day to consult together respecting the state and position of the general practitioner, one of their own class, for whom a draught had been prescribed by the Central Council of the Provincial Medical and Surgical Association,—a draught labelled “To Promote Uniformity of Medical Education and Qualification.” Let them uncork it, and they would find a strong smell of the tincture of collegiate ascendancy, of which it appeared to him to contain an over-dose. Let them test it accurately, and they would find in it scarcely a trace of that direct representative principle hitherto considered by the associated surgeons of this country as essential to the establishment of a healthy medical constitution. He would, with their permission, spoil a line of Horace, by the insertion of a single word; and in giving advice to their patient respecting the draught just prescribed, would say—

“*Hic haustus niger est, nunc, tu Romane, caveto.*”

It was the old black draught recommended by Sir James Graham in 1844 and 1845, but which the profession, acting under the advice of the surgeons of Shropshire and North Wales, very properly refused to swallow. He must say that he did not see that this Bill had any claim to their support, though it was true that some of the incidental clauses were very good, especially those which referred to the Provident Fund. By the present Bill they were not required to be members of the College of Surgeons, but still they were refused permission to practise in the army or navy, and were ineligible to hold any official appointment. The Bill was calculated to be injurious to some of the old medical institutions of the country, and he thought it was their duty to reform the old ones rather than establish an inferior grade. He would not hand over the right to examine to any body that would refuse him a control over that body. He had no opinion of forming a board for preliminary examination. He would not now make any further observations, as he would afterwards have something to propose for their consideration.

Mr. CARTWRIGHT, after some conversation, explained that the Bill was submitted to them for consideration, and maintained that it would, instead of lowering the profession, raise it much higher, by their having one common portal through which all candidates must pass, instead of about eighteen different ones. He maintained that in the constitution of the council they had ample guarantee of the high standing which it would give to the profession generally. It did appear to him that short of an election by the whole body of the members of the profession, and short of the adoption of the representative principle, they had in the proposed Bill as independent a body of men as could be selected to form the board; and, in his opinion, the board would perfectly represent the different classes of the profession, inasmuch as members of the Council would be chosen respectively from the Colleges of Physicians and Surgeons, and the Apothecaries' Company, which they had always regarded as the representative of the

general practitioner. He did not think it was possible to offer a more fair adjustment than what the Bill comprised. He had carefully investigated the clauses of it in reference to the principles advocated by the Parent Association; they were entirely in accordance with those principles and with every memorial and petition drawn up by the Shropshire Branch, and in particular with the proposals issued by Messrs. Brookes and Wood on the 28th of June, 1848, adopted at a subsequent meeting and laid by him before the Parliamentary Committee, viz., that the Colleges of Physicians and Surgeons, if properly modified, were sufficient for the requirements of the profession, and that no third College was necessary; also that the said Colleges should be empowered to appoint a Board of Examiners and institute a preliminary examination as a test of qualification, &c., &c. All this appeared to be accomplished in the present Bill. It was an actual absurdity to talk of the representative system not being carried out, since it is now liberally done in both of the proposed Charters for the Colleges of Physicians and Surgeons, on the adoption of which this Bill is contingent. In making the new medical council, they were not instituting a new College, but only an examining board, or board of management for the profession, and that too for corporate bodies, in which the representative system is already in existence. He also mentioned that when a person had become a licentiate with the necessary qualifications, he would, as a matter of course, seek to obtain the diploma of the College of Surgeons.

Dr. HENRY JOHNSON concurred in the view taken of the subject by Mr. Cartwright.

A lengthy discussion ensued as to the bearing which the proposed Act would have on the Colleges, and also as to the constitution of the council.

Dr. BAKEWELL gave his view of the case that the person would have first to pass as a licentiate, and might then take the higher grade of surgeon, &c.

Mr. PIDDUCK objected to the Council not being on the representative principle.

After a lengthy discussion, the opinion of the meeting was taken on the clause, and carried in its favour.

Mr. WOOD remarked that the Bill certainly did make three grades in the profession, but the students could, if they pleased, undergo a second examination by either the College of Surgeons, or the College of Physicians, and then be enfranchised. He was sorry to see that the Bill would in some measure affect the interests of the College of Surgeons, because it would make men competent to every possible emolument without being members of that College: He was afraid the College of Surgeons might object to it if it threatened any injury to their funds. He only made these observations with a view to making the Bill more efficient and more easily passed. If they run counter to the College of Surgeons, they would oppose the Bill by every means in their power.

There was some discussion on clause 13, the whole of the meeting concurring in the advisability of a Provident Fund being established, so that the members of the profession, their widows and children, should not be

left destitute; Mr. Cartwright instancing that such provision was made by the army, navy, and the East India Company, as mentioned by Dr. King in his beautiful address at Brighton.

Mr. KEATE contended that they were already licensed, and Messrs. PIDDUCK, BROOKES, and BAKEWELL, followed in the same line of argument.

Mr. CARTWRIGHT explained that when a new board was established, there must be something to pay expenses, and money must come from some quarter or other. No Bill had ever been brought forward that did not seek to tax the profession more or less.

Mr. WILDING concurred in the registration fee. With respect to the Provident Fund, the fact of its being compulsory was the essence of its excellence. Several parties appeared to object to their being required to register yearly, and thought it might be done on the first entry. It was, however, maintained and agreed to that the yearly registration would be a *safer protection* to the properly qualified practitioner, and a "*clencher*" to quackery.

The clause was then agreed to, and clause 14 next came under discussion,

Mr. PIDDUCK said he objected to the clause, because it was a palpable contradiction of clause 22. At the latter part of the clause in question he found the following:—"And every person to whom such licence shall have been granted as aforesaid, shall be entitled to assume the name and title of a licentiate in medicine, surgery, and midwifery." Then referring to clause 22, he found "That no person shall be entitled to assume the name or style of a physician who is not, in England, a member of the Royal College of Physicians of England, or in Scotland, a member of the Royal College of Physicians in Edinburgh, or in Ireland, a member of the King's and Queen's College of Physicians in Ireland; and no person shall be entitled to assume the name or style of a surgeon who is not, in England, a member of the Royal College of Surgeons of England," &c., &c. Now, then, they first of all examined the student, and said that he was qualified to practise in medicine, and then they said he was not qualified to practise. Why should he be compelled to go to another College before he could assume the title? Mr. PIDDUCK said that all he contended for was, that there should be surety for an efficient education, and that an examination should be made; and when that was undergone, that the student should bear the title of surgeon. There were only two titles known to the public—surgeon and physician—and if they took either of those titles from the practitioner they would degrade him.

Dr. BAKEWELL concurred with Mr. PIDDUCK.

Mr. WILDING asked why those who were members of the College of Surgeons went to that College at all? It was to gain a higher title. He presumed that all were licentiates; and he could not, for the life of him, see how it could degrade the practitioner.

Mr. BROOKES said what they had found so beneficial to themselves he should like to see handed down to posterity. He should like to see it made compulsory for the student to go to the College of Surgeons.

Mr. CARTWRIGHT thought that Mr. PIDDUCK would agree with him that the basis of everything that would produce an uniformity amongst them, and enable them to take each other by the hand, was education. By that Bill they would have uniformity of education. Every man would have to go before the same Board, and pass through the same examination, in order to receive his licence to practise. What was the case at present? Why, there were eighteen different means of getting a title that would authorise its possessor to practise. Would they tell him that a Board composed of all the heads of the Colleges, and united to form and superintend the education of students, was not more respectable than that of a mere trading company? They perfectly well knew that the College of Surgeons admitted men to the highest functions without any examination in medicine at all; and this Bill would, therefore, improve the College of Surgeons itself. He strongly protested against any one implying that it was *at the present time compulsory* for any one to become a member of the College of Surgeons; *it was well known that it was not so*. He thought it would be proper for the meeting to give their opinion on this point, in accordance with the request of the Worcester Council.

Mr. WOOD then proposed that licentiates should, in the opinion of this Branch, be compelled to become members of the College of Surgeons.

Mr. BROOKES seconded the proposition.

Mr. WOOD's amendment was then put to the vote, and carried by a considerable majority.

Mr. CLEMENT inquired if it would not be better to go to the Bill in general at once?

Mr. CARTWRIGHT moved the following resolution:—

"That this meeting of the Shropshire Branch of the Provincial Medical and Surgical Association, impressed with a deep conviction that it is essential to the best interests of the profession and the public that the question of Medical Reform be brought to issue, feel much gratification in the assurance that there is a fair chance of so desirable a result, in consequence of the Bill being brought forward in the name and by the authority of the Provincial Medical and Surgical Association. The members of the Shropshire Branch beg to express their hearty concurrence in the principles of the Bill, and in the just and equitable constitution of the Medical Council. They approve most highly of a Provident Fund, to which every medical man will hereafter have a claim, and which they regard as the best guarantee against that overwhelming affliction which is too often the lot of many who have to labour hard in a toilsome and ill-requited profession. Finally, regarding the Draft Bill as only provisional, the members of the Shropshire Branch beg to express an earnest wish that the Council will mature the measure, and carry it on to completion, satisfied that the profession at large will hail with gratitude the settlement of those differences and perplexities which have so long troubled its tranquillity."

Mr. WILDING, in seconding the resolution, begged to express his *admiration of the Bill*.

Mr. BROOKES could not bring himself to believe that the measure was a legitimate offspring for maintaining the honour of the profession. He objected to it because it was not based upon a fair representative

principle, and because he was convinced that it tended to degrade the future practitioner by instituting an inferior caste in the profession.

Mr. BROOKES proposed, and Mr. KEATE seconded, the following amendment :—

PROPOSALS FOR THE REFORM OF THE APOTHECARIES' COMPANY.

"First.—A new Act under the title of the Royal College of Medical Practitioners of England and Wales.

"Second.—The governing body to consist of twenty-four Councillors, to be chosen from among the electors of the said College; one fourth to go out of office either annually or triennially. The voting for the Council to be by balloting papers, transmitted by post.

"Third.—The Council to decide on the preliminary and professional education of candidates, and to appoint an Examining Board to examine in all branches of medical education, midwifery and surgery excepted, in which latter branches the candidate, before obtaining his licence to practise, shall be examined by the Royal College of Surgeons, of which he shall be a member.

"Fourth.—The electors for the Council of the said College of Medical Practitioners to consist—1st, of all medical and surgical practitioners, not possessing diplomas, but legally qualified by having been in practice prior to 1815. 2nd. All licentiates of the Apothecaries' Company. 3rd. All who, not possessing a licence from the Apothecaries' Company, are members only of the College of Surgeons. 4th. All persons hereafter licensed to practise medicine by the said College of Medical Practitioners, and surgery and midwifery by the College of Surgeons, and who shall be registered as surgeons and medical practitioners.

"Fifth.—The present governing body of the Apothecaries' Society to form part of the first Council, and the present Examiners to remain in office as long as they would under the existing Act of the Apothecaries' Society; but their number to be increased, if deemed necessary by the Council.

"Note.—The surgeon or general practitioner will thus have a voice in the management of his own medical college, and be enabled to secure for his own class a high standard of education—preliminary and professional. He will also be connected, as at present, by membership, with the College of Surgeons, of which institution he may also become an elector by taking the fellowship, for which honour every candidate for the licence to practise under the title of Surgeon, should be required to prepare himself in his education.

"Lastly.—A Council of Health and Medical Education to be formed of members of the Councils of the three Colleges, and of persons appointed by the Government, to be presided over by a Minister of Health, or by the Secretary of State for the Home Department. All plans for medical and surgical education to be submitted to such Council of Health and Medical Education, for their *veto*, if deemed by them of too low a standard, but not otherwise. Such council not to be empowered to appoint any examining board."

The PRESIDENT remarked that Mr. Brookes ought to have had this proposal printed and circulated among the members a week ago, for their private consideration.

Mr. CARTWRIGHT begged to congratulate Mr. Brookes on his new Apothecaries' College.

After some further discussion Mr. Brookes's amendment was put to the vote, and lost.

Mr. Cartwright's motion was then put and carried.

Dr. DRURY moved, and Dr. JOHNSON seconded, a vote of thanks to the Chairman, which was carried with acclamation.—The meeting then separated.

LANCASHIRE & CHESHIRE BRANCH.

At a special meeting of the LANCASHIRE AND CHESHIRE BRANCH of the Association, held at Newton-le-Willows, on the 11th of February, instant, JOSEPH DICKENSON, M.D., of Liverpool, in the chair,

It was proposed by Mr. NOBLE, of Manchester, seconded by Mr. MEDD, of Stockport, and carried unanimously,

"That this meeting of the Lancashire and Cheshire Branch of the Provincial Medical and Surgical Association, after maturely considering the Medical Bill referred to them by the Worcester Council, and published in the *Provincial Medical and Surgical Journal*, is of opinion that such Bill faithfully represents the principles of Medical Reform so long advocated by the Association, and is worthy of the cordial support of every member of that body."

Moved by Mr. SOUTHAM, of Manchester, seconded by Mr. DUNSTAN, of Holmes Chapel, and carried unanimously,

"That this meeting recommends the framers of the Bill to persevere in their endeavour to pass it into a law, with such alterations in the details as circumstances may require, and trusts that the members of the Association will exert themselves in their several localities to induce Members of Parliament to take an interest in the passing of this measure, so important to the welfare of the profession and of the public."

After these resolutions had been carried by acclamation, the Honorary Secretary read the different clauses of the Bill *seriatim*, and an interesting discussion ensued.

The Bill, as a whole, was highly approved of; and the Secretary was requested to express to the Central Council at Worcester the high approval of the meeting of the Provident Fund, and the uses to which any surplus provided by the 19th clause may be applied.

They also requested him to inquire whether the 22nd clause inculcates the necessity of *all* graduates in medicine becoming *members* of the different metropolitan Colleges; and whether this clause is intended to include graduates of Oxford and Cambridge, who already possess peculiar privileges.

To clause 25th it was thought desirable to include merchant and emigrant vessels professing to carry a surgeon, as many known abuses had existed from the want of such provision.

Mr. Medd having taken the vacated chair, it was carried by acclamation, "That the best thanks of this meeting be given to Dr. Dickenson for his kind and impartial conduct in the chair.

JOSEPH DICKENSON, M.D., Chairman.

JOHN HATTON, Honorary Secretary.

MIDLAND BRANCH.

MEETING AT DERBY.

At a meeting of the Members of the Provincial Medical and Surgical Association, held on the 10th instant, at the Philosophical Society's Rooms, in DERBY, to consider the provisions of the Draft Bill for Medical Reform, the members present were unanimously of opinion that the Bill, if carried into effect, is calculated to elevate the *status* of our profession, and to confer important blessings upon the community.

A general determination was also expressed to aid, by all practicable means, the progress of the Bill in Parliament.

S. W. FEARN, Hon. Sec.

MEETING AT NOTTINGHAM.

At a meeting of the NOTTINGHAM AND NOTTINGHAMSHIRE DIVISION of this Branch of the Association, Dr. J. C. WILLIAMS in the chair, the "Draft Bill To Produce Uniformity of Medical Education and Qualification, and for the Registration of those Licensed to Practise in Medicine" having been considered,

It was resolved unanimously,—

"That the same be recommended for adoption as a satisfactory basis of a bill for the regulation of the medical profession, so soon as the Royal Colleges of Physician and Surgeons of England shall have obtained amended Charters."

YORKSHIRE BRANCH

MEETING AT HULL.

A MEETING of the members of the Provincial Medical and Surgical Association resident in Hull and the neighbourhood was held at the Hull Infirmary, February 10, 1852, to consider the proposed Medical Reform Bill.

Present,—Dr. HORNER, Vice-President of the Association, in the chair; W. H. EDDIE, Esq., of Barton; Drs. COOPER and LUNN, Messrs. HARDEY and LOCKING, of Hull, &c.,

It was unanimously resolved,—

"That this meeting views with much satisfaction the Medical Reform Bill, proposed by the Council of the Provincial Medical and Surgical Association, and is of opinion that its provisions and principles are calculated to ameliorate the position and satisfy the requirements of the profession."

Letters to the same effect were read from Dr. SANDWITH, of Hull, and Messrs. GAGGS and MEDCALFE of Howden.

GENERAL MEETING OF THE PROFESSION AT NOTTINGHAM.

At an influential meeting of the profession generally in Nottingham and its neighbourhood, Dr. WILLIAMS in the chair, after maturely considering the clauses of the Draft Bill, on the motion of Dr. HUTCHINSON, and seconded by John Northon Thompson, Esq.,

It was resolved unanimously,—

"That this meeting highly approves of the general principles of the Bill proposed by the Council of the Provincial Medical and Surgical Association, and recommends its adoption by the profession."

In the discussion which ensued on the several clauses contained in the Bill, the accompanying suggestions and alterations were agreed to as being required for the due working of the measure. We take the following from an abridged report of the meeting furnished by the Secretary of the Branch:—

Clause 13.—For England and Wales read England or Wales. This clause, which is retrospective, does not compel registration, but permits it only, therefore it will be inoperative.

Clause 14.—The following brief addition was suggested:—"Unless able to prove his title to registration under clause 13."

Clause 14.—It was thought this clause does not state

sufficiently clearly that medical men qualified previously to the passing of this Bill are at liberty to practise if the registration fee has not been regularly paid.

Clause 21.—It was thought this clause should give to the members of the Royal Colleges of Physicians and the Royal Colleges of Surgeons in England, Scotland, or Ireland respectively, reciprocity of privileges in case of transfer of residence.

Clause 22.—The wording of this clause is insufficiently explicit, and appears to require members to practise in their respective countries, where their diplomas are obtained.

Clause 23.—Read visits or medicines instead of visits and medicines.

Clause 26.—A query was put on this clause—"Who shall be the informer?"

At the conclusion of the meeting it was proposed by Dr. MASSEY, and seconded by Henry Taylor, Esq.,—

"That this meeting begs to offer its thanks to the Council of the Provincial Medical and Surgical Association, for the ability displayed and the trouble they have taken in drawing out and laying the Bill before the profession."

It was also proposed by Joseph White, Esq., and seconded by B. EDDISON, Esq.,—

"That the thanks of the meeting be given to Dr. WILLIAMS for his valuable services as chairman."

In connection with the foregoing we extract the following remarks from a letter received from A. DARBY, Esq., Secretary:—

"That there should be a Registrar in every county town to look after irregular practitioners."

"Clause 13 should run somewhat to this effect:—That the Registrar or Registrars of each of the said Boards shall, within thirty days of his or their appointment, and shall from time to time, till the first day of February, 1853, require all legally qualified persons to be registered in books to be kept for that purpose, and to pay a fee of five shillings, &c. &c.,

"With something of the kind Clause 26 may be operative."

"Clause 16.—'How are the advantages to be obtained?'"

EAST KENT & CANTERBURY MEDICAL SOCIETY.

SESSION 1851-52.—SECOND MEETING, JAN. 2, 1852.

Pathological specimens relating to the following cases were exhibited:—

An Aneurism of the Arch of the Aorta bursting into the Trachea by two openings and involving the Recurrent Nerve, so as to produce symptoms resembling Chronic Laryngitis.—By Dr. GOOCH.

The paper relating to this case will be found at page 87 of the *Journal*. In the conversation which followed the relation of this case, and in connection with the position of aneurism in the first portion of the aorta, Dr. LOCHEE exhibited a specimen of a diseased aorta, in which an aneurism had formed in the pouch behind one of the semilunar valves.

Mr. W. R. SMYTH mentioned a case connected with the encroachment of aneurism upon other organs, in which a person died suddenly, with some previous evidence of venous obstruction, and it was found that an abdominal aneurism had burst into the vena cava.

In relation to the occasional absence of bruit in an

aneurism, Mr. HALLOWES related an interesting case that had occurred in the hospital. A man was admitted with a firm swelling in the popliteal space. No pulsation could be detected in it by the repeated examinations of different observers, and no bruit was heard by as frequent applications of the stethoscope. The case had been sent as one of popliteal aneurism; the investigation was, therefore, minutely and accurately conducted, yet nothing but a tumour of uncertain nature could be made of it. After a time, the integument over it became red, and suppuration appeared to have taken place; a lancet was introduced but nothing followed. Several hours after, a sudden gush of blood occurred, and before assistance could be rendered the man died. At a *post-mortem* examination, an aneurism, filled with concentric laminæ, was found connected with the popliteal artery.

Two Tumours removed from the front of the Chest and the Back, associated with Cancer of the Forearm.—
By Mr. P. B. HALLOWES.

S. M., aged 40, is married and has borne children. Her complexion is fair, and of late rather sallow. Her health was never robust. About six years since she noticed a small hard lump of the size of a pea in the integument of the inner surface of the left forearm, nearly midway between the wrist and the bend of the elbow. A slight occasional pricking sensation was the only uneasiness felt. The lump slowly increased, and after it had existed three years she became an out-patient of the Canterbury Hospital, under the care of Mr. Reid. There was then a flat circular growth with rounded edges, raised above the general surface nearly a quarter of an inch. It was about the size of a sixpence, and the centre was depressed and ulcerated. Strong nitric acid, and ultimately potassa fusa were applied. It required five or six applications of the caustics before all traces of the disease were removed, and a healthy surface produced. A deep ulceration was caused by the remedies, but the sore healed soundly. About six months afterwards, the disease returned in the cicatrix, and one or two lumps appeared in various parts of the body, and increased in size. She applied to Mr. Hallowes about eighteen months since, when there appeared, arising from the cicatrix on the arm, a growth of fungoid appearance, but not showing a malignant character. It was attached to the arm by a broad base, and immediately from its origin spread with prominent and everted edges in a circular form, so that a probe could be passed from its edges some distance before it reached the base. The surface was unequal, scooped out in parts, projecting in others; the hollowed portions were ulcerated, and discharged a thin, colourless, inodorous fluid; the raised portions were covered by a very delicate transparent membrane, on which small blood vessels were beautifully ramified. There has been little alteration in the character of this growth up to the present time, except its increase of size, and an occasional slight hæmorrhage. Various applications—nitric acid, muriatic acid, arsenic, &c., have been made for its destruction, but without effect.

The tumours on the body continued to grow, some attaining the size of four or five inches in length by two or three in breadth; one on the chest seemed to be advancing to suppuration; the skin covering it was inflamed and slightly adherent. This was removed, and was found to consist of a firm homogeneous structure, of a density between that of a fibrous and scirrhus growth; it had a whitish colour and glistening aspect, with an appearance of being slightly lobed; at one or two points a small yellowish grey deposit was noticed, and under the spot where the integuments were inflamed there was an irregular cavity of the size of a hazel nut, containing some apparently well-formed pus. Another tumour of large size, removed from the back, resembled the above in all its characters, with the exception that there was no purulent deposit.

The great amount of constitutional disturbance following the operation, and the length of time which ensued before the patient recovered her health, deterred Mr. Hallowes from removing the other tumours, six in number. Since the operation, two small additional growths have appeared.

From a full consideration of this case, Mr. Hallowes was inclined to think that organic disease would ultimately destroy life, and that the liver would be its seat, unless the tumours should suppurate, and be succeeded by growths similar to that on the arm, in which case it is probable the health would be worn down by the discharge and irritation.

Several months after her discharge from the hospital, and since the case was related, Mr. Hallowes was called to visit her in the country, and learnt the following particulars:—Additional tumours had appeared in the loins and back; the original tumour on the arm had much increased, and become very painful; her health had slowly failed; great emaciation, followed by ascites, had taken place. At the period of his visit she was generally anasarous, especially about the face, and was suffering much pain in the head and chest, with palpitation of the heart, and was at times delirious. She died a fortnight afterwards. No examination was obtained.

Placenta Prævia.—By Mr. A. B. ANDREWS.

Mr. A. B. Andrews presented a placenta, with the membranes entire, and containing a foetus between the fifth and sixth month of development. The placenta was dark, and injected with blood throughout the greater part of its extent, and numerous coagula were entangled in, and adherent to its surface. A defined line separated this portion from the remainder, and indicated the extent to which it had been placed over the os uteri. The patient was 41 years old, and had borne seven children. At the third period, when menstruation would have occurred had she not been pregnant, hæmorrhage had taken place, and continued for a week, and then ceased until the fourth period, when it recurred, and continued more or less until she miscarried, which was about a week after the fifth period. The hæmorrhage was at this time very considerable, but ceased after the expulsion, in one mass, of placenta

and membranes, with the foetus. She had a good recovery.

Warty Ulcer, or Epithelial Cancer of the Cicatrix of a Burn.—By MR. JAMES REID.

This case, with two others, and some observations relating to the disease, has been published at page 62 of this journal.

PATHOLOGICAL SOCIETY OF LONDON.

DR. LATHAM, PRESIDENT, IN THE CHAIR.

DR. JENNER presented specimens of

Crimson or Hæmatoid Crystals (of Virchow), and Calcification of the Minute Arteries of the Cerebrum.

The beautiful rhomboidal crystals under the microscope were obtained, Dr. Jenner stated, from what appeared to be an old clot in the right corpus striatum, and white matter adjacent, of a woman about 60 years of age. Although these bodies were first figured by Sir Everard Home, they were not fully described in detail till Virchow published his memoir on Morbid Pigment in the first volume of his "Archives für Anat. Pathol." Under the microscope might also be seen much orange-coloured, amorphous, and more or less granular matter, in which the crimson crystals lie. Both the orange-coloured granules and the red crystals are, Virchow states, modifications of hæmatosin, and, therefore, he terms the latter hæmatoid crystals. Independent of the interest which their appearance might excite, they are probably of some practical importance, for it would seem that, whether really, as Virchow states, a crystalline form of hæmatosin or not, they are never found unless preceded by stasis of blood; and that several days, perhaps weeks, are required for their formation. The earliest period at which Virchow knew them to be found was seventeen days. This was in the case of an individual who received an injury whereby extravasation of blood was produced. With reference to the case from which the crystals under the microscope were obtained, it was a matter of great interest to determine the age of the clot. The woman had had no paralysis of the left arm or leg, and very trifling loss of power in the muscles of the left side of the face. She died from apoplexy, with right hemiplegia, of two days' duration. An evidently recent clot occupied the left corpus striatum and optic thalamus, and a clot of considerable size, having a somewhat orange colour, and containing the crimson crystals, a part of the left corpus striatum and adjacent white substance. Now, what was the age of the clot on the right side? Was this woman walking about without any signs of paralysis of the left arm or leg, with a large clot in the right corpus striatum and white matter adjacent? Many of the minute arteries in the corpora striata, and a few in the white matter of both hemispheres were, in the same subject, the seat of a deposit of calcareous matter. The deposit was in some cases limited to the middle

coat, and in several the calcareous matter existed in the form of minute granules, giving only a clouded appearance to the coat. Hydrochloric acid dissolved the calcareous matter, giving off bubbles of gas, probably carbonic acid. The coats of the arteries, after the action of the acid, looked perfectly healthy. The walls of a few of the capillaries were studded with fat. Some of these calcified, and also many of the apparently healthy minute vessels of the white substance of the hemispheres were filled with orange-coloured granules, no blood-discs being perceptible among them. Dr. Jenner thought these granules had been formed during life, as a consequence of congestion, from which the patient had been supposed to suffer, and that their presence must seriously have interfered with the circulation through, and consequently with the functions of, the cerebrum. He adverted to a case that lately fell under his observation, in which the external coat of the minute arteries of the brain was greatly thickened by fibrous tissue, and to the effect on the cerebral function which this condition might have produced.

Dr. BALY referred to a paper on the anatomy of thrombus by Sir E. Home, in which these bodies are spoken of as being found after a certain period; so long a period, indeed, that he (Dr. Baly) thought they must in Dr. Jenner's case, be referred to the earlier date.

Mr. SOLLY inquired of Dr. Jenner, how much of the corpus striatum and optic thalamus had been left intact on the right side? The question he thought interesting in a physiological point of view.

Dr. JENNER read that portion of the case which referred to this point; from which it appeared that about three-fourths of those bodies were normal.

Mr. SOLLY remarked, that it was interesting to notice how much of these bodies could be destroyed without the occurrence of paralysis.

Mr. SOLLY represented a specimen of

Necrosis of a Portion of the Head and Neck of the Thigh Bone.

The sequestrum is about an inch in length and half an inch in breadth. It is quite detached from the sound bone. The cavity in which it is contained occupies the neck and head of the femur, and the centre of the articulating surface of the head of the bone is quite absorbed. The joint is obliterated by the absorption of all the cartilaginous surfaces and synovial membrane. The head and neck of the femur are fully united to the pelvis by a firm fibrous tissue, forming a complete but not osseous ankylosis. On the anterior surface of the neck of the bone, just in front of the anterior intertrochanteric line, there is an opening through the sound cancellous structure about the size of a horse-bean. This allowed the exit of the pus into a fistulous abscess, which runs behind the tendon of the rectus to the outer side of the thigh. The subject of this disease was a young woman, aged 32, who was under Mr. Solly's care in St. Thomas' Hospital. She traced the disease to an injury received when she was 12 years old. Nine years ago she was under Mr. Solly's care, and the disease of the joint was so far arrested that she was able to walk

well and without pain with a high shoe; but she abandoned the use of it, not liking its appearance, and got fresh inflammation in the joint, but remained suffering for some years without any medical treatment. She died with ulceration of the intestines, with a large fatty liver, and disease of the ovary. Mr. Solly considered that the necrosis was consequent on the supply of blood being partly cut off by the ligamentum teres, and the obstruction of the other arteries of the head of the bone by general inflammation of its cancellous tissue. Mr. Solly remarked, that if the health and general power of the patient when she went into the Hospital had warranted any operation involving loss of blood, and the exact condition of the necrosed portion could have been ascertained during life, it might have been removed by a little enlargement of the osseous structure.

Mr. SOLLY inquired of Mr. Stanley whether, in his experience, he had met with such a case as that he (Mr. Solly) had just related.

Mr. STANLEY, in reply, asked Mr. Solly which, in his opinion, was the original malady, the diseased hip-joint or the necrosis.

Mr. SOLLY believed that the disease originated in the synovial membrane of the hip-joint, and that ultimately necrosis of the femur occurred. Such was his opinion, but, unfortunately, he had not been able to obtain such information respecting the case as to satisfy his mind that his opinion was quite correct.

Mr. STANLEY replied, that it would be of course difficult to make out such matters quite satisfactorily. He had met with such cases, and generally in females from 20 to 25 years of age; there would be sinuses discharging freely for years, and considerable suffering. The probe passed in deeply, and struck upon dead bone, but the evidence of its being loose was not usually satisfactory. If such were discovered during life, it would be right to attempt its removal, but not otherwise.

Mr. WM. ADAMS exhibited for Mr. Mackmurdo a specimen of

Extensive Laceration of the Liver, which the Patient Survived Seven Weeks.

J. W., aged 23, admitted into St. Thomas's Hospital in a state of extreme collapse, having been squeezed between a cart-wheel and a post. He remained without any re-action for nearly forty-eight hours, and then slowly revived, having taken a very large quantity of brandy. Symptoms of peritonitis supervened, and were somewhat relieved by calomel, &c. The abdomen remained swollen, with distinct fluctuation on the right side. Oppression at the chest, with difficulty of breathing, gradually increased, till his death, which took place seven weeks and two days after the accident.

Post-mortem examination.—Right side of the chest more prominent than the left. Abdomen uniformly tense. On opening the chest the right pleural cavity appeared to be filled with turbid serum, tinged with blood, in which was a large quantity of imperfectly coagulated blood, about a quart, coated with fibrin or lymph, tinged with bile. The right lung had evidently suffered extreme compression. This fluid also commu-

nicated with fluid in the abdominal cavity, through what at first appeared to be a laceration in the diaphragm; further dissection, however, showed that the fluid in the chest was not in the pleural cavity, but that the diaphragm had been pushed upwards into the chest as high as the upper edge of the third rib anteriorly and laterally, and internally to the interval between the second and third dorsal vertebræ; below the points indicated it was adherent to the thoracic parietes. The right lung was compressed into the apex and posterior part of the thoracic cavity, the anterior margin of its base not extending lower than the interval between the second and third costal cartilages. The substance of the lung was healthy. Continuous with this thoracic extension of the abdominal cavity was a large and imperfectly-circumscribed cavity, occupying nearly the right half of the abdomen, bounded below and towards the mesial line by the great omentum, passing obliquely downwards across the right iliac fossa; in this situation the boundary was imperfect, so that the large cavity above described as occupying the right thoracic and right half of the abdominal regions, communicated with a smaller cavity occupying the pelvis, and extending into the left iliac region, and also filled with serum, turbid with pus, the pus being most abundant in the iliac region. These cavities were circumscribed by peritoneal adhesions. There had been slight general peritonitis, a small quantity of lymph being diffused over the surface of the intestines, but the adhesions were principally in the neighbourhood of the cavities above described. The liver was lacerated extensively, the injury extending nearly through the centre of the right lobe, the outer portion of which, nearly detached, was displaced upwards, lying over the heads of the sixth, seventh, and eighth ribs; this portion was of a very light yellow colour on the surface, and extremely pale in its interior. The laceration ran parallel for a considerable distance with one of the largest branches of the right hepatic vein, but no branch of the first or second order appeared to have been opened, though the laceration extended almost to the vena cava. The liver was tilted towards the right side, and one margin of the laceration being drawn towards the ribs, contributed to the deceptive appearance of a laceration through the diaphragm. All the other organs were healthy, with the exception of a very slight laceration of the right kidney.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

Researches on the Structure of the Spinal Cord.—By LOCKHART CLARKE, Esq.

Some new and independent observations on the minute anatomy of the spinal cord have been published by Mr. Clarke, which lead to the following inferences:—

1. That the posterior grey substance at the lower extremity, and in the dorsal region of the cord, consists only of a single mass; and that the *substantia*

gelatinosa extends uninterruptedly across from one side to the other.

2. That the nerve fibres of the grey substance, including those of the *substantia gelatinosa*, are not grey fibres bearing nuclei, like those of the sympathetic, but fine tubules.

3. That two considerable columns of caudate vesicles (*posterior vesicular columns*), in intimate connection with the posterior roots of the nerves, extend the whole length of the cord; commencing small at its lower extremity, increasing in size in the lumbar and cervical enlargements, and terminating at the upper part of the medulla oblongata.

4. That the number of caudate vesicles, particularly in the anterior grey substance, is in direct proportion to the size of the nerves.

5. That the column of vesicles, into which, in the cervical region, the spinal accessory nerve may be traced, extends down the cord as far as the lumbar enlargement.

6. That a considerable branch of the spinal accessory nerve, which is the only nerve immediately attached to the lateral column, after entering the grey substance, may easily be traced to the caudate vesicles of the anterior corner.

7. That the posterior roots of the spinal nerves are immediately attached to the posterior white columns only, and the anterior roots to the anterior columns only; but that fibres from both these roots, after traversing certain portions of the grey substance, pass again into the white columns.

8. That neither the anterior nor posterior white columns are connected by a transverse commissure.

9. That the central portion of the grey substance immediately surrounding the spinal canal is not a commissural structure, but is a layer of fine fibrous tissue for supporting the walls of the canal, which is lined with columnar epithelium.—*Philosophical Transactions*, Part II., 1851.

Observations on the Sounds of the Heart.—By R. BROWN, Esq., M.R.C.S., L.A.C., &c.

The author of this communication disputes the generally-admitted theory of the heart's action. After giving a brief *résumé* of the opinions of Laennec, Hope, Williams, &c., he says:—On applying the ear or a stethoscope over the præcordial region, two sounds are heard following each other; the first is dull and prolonged, whilst the second is shorter and sharper. The first sound is produced during the diastole, and the second during the systole of the ventricles; and in support of this theory I will briefly state the circumstances under which this opinion was formed.

Some few weeks since, attending a patient labouring under increased action of the heart, and whilst conducting an examination, I could distinctly appreciate the inward current of blood from the auricle to the ventricle, producing the first sound by suddenly distending this latter cavity. The apex of the heart striking against the walls of the chest in the neighbourhood of the fifth and sixth ribs, communicated to the ear at this moment a shock (the heart's impulse). Immediately followed the second sound, produced by the onward current of blood through the aortic opening, propelled

by the contraction of the ventricles. I observed, moreover, that the first sound did not exceed the space in which the impulse was felt, but that the second sound was audible in nearly the whole extent of the chest, which would tend to strengthen the theory I have advanced, inasmuch as the sound produced by the diastole of the ventricle would be circumscribed, whereas that produced by the systole would be diffused.—*Lancet*, Jan. 3, 1852.

PRACTICAL MEDICINE.

On the Varieties of Alkaline Urine.—By Dr. B. JONES.

It is of some importance to diagnose the exact origin of alkalinity in the urine, inasmuch as the prognosis and treatment widely differs. This is clearly set forth in some lectures by Dr. Bence Jones in the *Medical Times*.

The differences between ammoniacal and alkaline urine are mentioned in the following table:—

Contrast between—

Ammoniacal Urine	and	Alkaline Urine.
Alkalescence from carbonate of ammonia.		Alkalescence from fixed alkali.
Caused by local disease.		Caused by general disorder.
Blue paper made red on drying.		Blue paper remains blue on drying.
Alkalescence is constant.		Alkalescence is occasional.
Excess of mucus and pus present.		No pus. Rarely much mucus.
Prismatic crystals generally seen.		At first granular deposit only seen.
The iridescent film has prismatic crystals.		The iridescent film consists of thin plates.

The alkalescence of ammoniacal urine, Dr. Jones continues, is caused by carbonate of ammonia. It arises from local disease,—from some altered mucus setting up a change in the urea, and giving rise to carbonate of ammonia. *When tested by blue paper it is made red on drying.* The alkalescence is generally found to be constantly present for days or weeks together. The local disease consists in inflammation of the mucous membrane of the bladder, which gives rise to an excess of mucus, and frequently to pus. In the sediment prismatic crystals are constantly seen. If the urine is left to stand, an iridescent scum forms on the surface, giving all the prismatic colours, and in the film distinct prismatic crystals can be found. The difference when the urine is alkaline from fixed alkali is great. It is caused by general disorder, as indigestion, which is not a derangement of the stomach alone, but a disorder of the whole system. *When tested with blue paper, it remains blue when the paper is dried.* The alkalescence is only occasional, lasting usually a few hours. No pus can be found, and there is rarely much mucus present. There are sometimes oxalate of lime crystals present, but these are very variable. In many points such urine differs thus from ammoniacal urine; the most striking difference is the absence of pus, and of an excess of mucus. But there are other points of difference still to be mentioned. In urine alkaline from fixed alkali, the precipitate which forms at first consists only of a granular deposit of phosphate of lime. Usually there is no appearance of prismatic crystals at all until the urine has stood for some time. The iridescent film, if examined with a microscope, will not be found to consist of prismatic crystals, but of fine thin plates of phosphate of lime, which are perfectly soluble in any acid, and have no crystalline

appearance. If these facts are true, then what has been called the phosphatic diathesis, should be called alkaline urine; and this must be subdivided into two very different states, the one ammoniacal urine, and the other urine alkaline from fixed alkali. As the causes which produce these states are totally different, the practical importance of the distinction cannot be overlooked.

[The presence of prismatic crystals in the iridescent pellicle is not strictly characteristic of ammoniacal urine, we have repeatedly met with them so large as to be visible to the naked eye, in the pellicle which forms in the urine of patient's labouring under irritative dyspepsia.—Ed. P. J.]

Bleeding and Colchicum in Acute Rheumatism.—By
DR. ALDIS.

Dr. Aldis relates a case of acute rheumatism in a female, aged 53, which he treated by bleeding to eight ounces, calomel and opium at night, and colchicum and sulphate of magnesia. The recovery was rapid. As medical opinion is somewhat divided on the best treatment for this disease, we subjoin the author's comments. He observes that he learnt the way of treating rheumatism from Dr. Chambers, and has himself had twenty-four years experience of it. He has also tried other modes of treatment, but prefers this. It has been objected that bleeding debilitates the patient very much, and that calomel salivates. To this he replies that it is not necessary to push bleeding so far as to occasion the first; and with regard to the second, he never salivates the patient, unless pericarditis is present. It has been asserted that venesection produces pericarditis; of this the author never saw a single instance; but he has seen numerous cases of chronic pericarditis, in which venesection had never been used. It is, however, quite true that, in spite of active antiphlogistic treatment, pericarditis may supervene; nevertheless, he believes it is much oftener cured or relieved when met by antiphlogistic treatment. From the frequent coincidence of pericarditis with acute rheumatism, the vitiated state of the secretions, and the painful nature of the disease, the author strongly recommends the above mode of treatment, being, as he believes, a judicious combination of powerful and valuable remedies, calculated to fulfil the indications required for treating the complaint. He only remembers two cases where the venesection caused even temporary distress, the patients had been addicted to drinking, and slight delirium tremens was induced.—*Lancet*, Jan. 10, 1852.

SURGERY.

Fatal Tetanus following Ligature of Hemorrhoids.

By JAMES BOLTON, M.D.

Dr. Bolton relates the case of a negress in whom the operation for piles was thus performed:—The patient was fully narcotised by chloroform. The hæmorrhoidal mass was so vascular that merely sponging with cold water caused the loss of about half a pint of blood in a few minutes. It was divided by sulci into three tumours. A needle was passed through the base of each, carrying a double ligature, which was tied on both sides of the tumour. In forty-eight hours nearly the whole had sloughed off. Chlorine wash was applied to

correct the fætor and to promote healthy action. A moderate dose of sulphur and bitartrate of potash was ordered, to remove constipation caused by opium used to allay the pain which was produced by the ligatures. About three or four times the quantity ordered was given, and produced violent hypercatharsis. This was not checked until it had lasted several days, owing to neglect of directions. On the fifth day the patient felt remarkably well until night, when she suffered from cramps of the ham's. Next day there were symptoms of decided tetanus. Ordered morphine sulph. gr. ss.; quinine disulph. gr. x., every second hour. Chloroform to be used as often as necessary, to subdue spasm. Direction not attended to until night. Observing some fætor from the anus, applied injection of strong solution of nitrate of silver. The following day the spasms continued, when free from the influence of chloroform; some tendency to sink; inability to swallow. Directed mercurial inunction extensively. After relaxing the patient completely by chloroform, passed a stomach tube and injected morphine sulph. gr. j.; quinine sulphate, dr. j., and brandy, *css.* Only one spasm occurred after this, but the patient continued to sink, and died without a struggle in about four hours. A *post-mortem* examination was not permitted.—*Stethoscope* (U.S.) *Journal*.

On the Local Treatment of Suppurating Joints.

[Surgeons in general are averse to making incisions into joints, under a vague impression that the contact of air is prejudicial. The fallacy of such impressions so clearly demonstrated by Mr. Gay, is also exhibited by Mr. Solly, in some clinical remarks or injuries of the knee-joint. He says:—]

With regard to the local treatment, I have no hesitation in recommending a free opening into the joint, where there is extensive suppuration, and much constitutional irritation in consequence; and on this subject I think the opinion of Mr. Rutherford Alcock of infinite value, from his great experience. He says:—

"The great object, then, is, firstly, to prevent the deposit and accumulation of matter in the articulation, which, notwithstanding all that has been said of its bland, innocuous nature, previously to the admission of atmospheric air, quickly erodes all the articulating surfaces, in the generality of cases; I have seen exceptions but they are few; and, secondly, to prevent the matter from burrowing among the muscles extending upwards and downwards, thus involving the whole limb in a suppurative and disorganizing disease.

"No sooner, therefore, is suppuration established, than it becomes necessary to devise the best means of obtaining its evacuation, and to secure its draining off, in proportion, or as fast as it forms. Any fears of the contact of air, I cannot but think, are out of place. The matter will do more mischief by being allowed to lodge. Counter openings in pendant positions, and free incisions, either in the vicinity, or, if necessary, through the capsule, should be promptly and boldly practised, together with such regulated pressure, above and below the articulation, as the state of the limb may indicate and allow, in order to counteract the tendency to spread and burrow."—*Lancet*, January 10th, 1852.

Correspondence.

TREATMENT OF THE INSANE.

To the Editors of the *Provincial Medical and Surgical Journal*.

Sir,—Dr. Munro favoured me with a little Greek: his Latin quotation I had somewhat to correct; and I may perhaps find out who can best construe the verb—*αμαρτανω*. I will now present him with a little German.

“Der erste Fehler des Menschenist, das er Theorien fur Erfahrungen nimmt; der zweite das er *Seine* Erfahrungen fur alle halt.”

I am sorry your opinions differ from mine: but fairness and courtesy is all I can require in discussion. I write from a review of opinions formed upon an experience of thirty-five years, as a student and a practitioner in this branch of medicine. I write, therefore with some confidence in the matter upon which I dissertate.

To what does my argument tend? Truly that the cure, relief, proper care of insanity, is not to be trusted to honourable and experienced minds, but that all who engage in it, are to be suspected of fraudulent motives, self interest, unjust suspicions, a desire of retarding, instead of promoting cure; whereas the best advertisement of a private asylum is the number it restores to society and to their social duties. My greatest pleasure is, when I can say my patient is recovered, and I am certain this is a general feeling; but I will contend, the minute observation practised as the law requires, often throws back the patients, often engenders angry feelings, is often subversive of good order, and of that intimate relation which ought to subsist between patients, attendants, and the superior, upon whom all the responsibility devolves. That the patients friends are often hurt by this machinery, I have no doubt.

In former days, the facility of confinement might be too lax, but whenever reform, so called, is instituted, it frequently passes to an extreme, and both common sense and common intelligence are sacrificed.

To what does all this tend?—as if every one would not have greater pleasure in showing a clean than a dirty house, and would not prefer a sociable to a turbulent dwelling.

I am sure this minute inspection could not be suffered in any private domicile. Perhaps a dirty patient may be fouled at the very moment of the Commissioners' visit—perhaps the visit may have caused the circumstance—as has occurred in one of the best-regulated establishments in the kingdom, down goes a note, which has to be reported, that there is an offensive smell. An early visit may be made before the rooms can be cleaned, and the report is made. Surely this is sufficient to provoke, when every house in Europe, if subjected to such investigation, might be equally taunted.

The complaints of grumbling patients are often much more attended to, than their reality can admit; if the Commissioners would observe the condition of the other patients, taste the cup or food complained of, their judgment would generally be properly determined.

The case book does certainly afford some protection, but though absolutely insisted upon under a fine of not being adequately kept, is not always believed.

Why, again I ask, are we—the proprietors of private asylums, to be submitted to such subordinate inquiries, and why are we to be suspected of conduct, that can only apply to felon prisons, or to inhuman governors of houses of correction?

Take the level of this proprietary system, and there will be found in it, that class that would desire to do unto others, as they would wish should be done unto themselves.

I repeat, I am sorry we differ, but my regret diminishes as I read the words of your quotation in your leading article. The “recent writer,” I know not. His sentences are highly figurative, also highly delusive; they might adorn a novel;—well mouthed, might move an audience to tears;—in reality, *nothing*. I could turn them into a song of a poetical maniac, and I believe could quote them from a book in my library, entitled “The Maniac’s Hall.” Permit me also a quotation:—

“The proper study is to guide the mind,
From ills supposed, or fancies unconfined.
To bring its actions to their proper course,
Neither too eager, nor too weak their force.
Check sudden Elysium, melancholic tears.
Wild wand’ring thought, or nightmares’ horrid fears.

“Ah! what avails, when reason’s lost its power,
But gently try to calm the present hour,
Urge nobler motives, but impress not much,
Vain is your guidance, be your plan not such.
This is our proper duty, this the plan,
To prove the study of mankind is man!”

These are noble lines, and worth all the day dreams of rhapsody. What! can it be believed for a moment, that any part of a private asylum is a dungeon, where no ray of hope enters!—where the starling sings to the miserable captive!—where the iron enters into the soul? Alas!—alas! that I should write these words, and that the leader of a journal, I so estimate, should force me to do so.

“And yet they are all brethren.” True; but are we all the same in intelligence, in equality of faculties—of mind—physical force, in ability of direction, in what God, as a general law of humanity, has consigned to his work. Then, away with every system—every code of laws that is or may be formed to unite the social circle for the purpose of general advantage, either in religion, property, or disease. The rivers flow, the tide alternates: these are obvious to our senses. What can the writer mean by his “Ocean of Eternity.”

It cannot be denied that all treatment, must be guided by the moods of insanity. View the conditions of private life. Melancholy will not be subdued by laughter; a paroxysm of rage by oily words of persuasion; nor the giddy flights of an hysterical girl by reading her a long sermon. So in the various phases of insanity, amusement will not amuse, kindness will be treated with insult, indulgence with contempt; and these feelings, when in abeyance, are often re-excited by the visits of either Commissioners or of relatives. I could cite many examples, and some of our most sensible writers lay much stress upon the prevention of frequent communication. Yet I know, and have known, many very happy in these “hopeless rayless prisons;” many desirous to remain, many after their cure, repeatedly

visiting their former habitation, and partaking of the family meal.

I object entirely to the plan propounded. I consider it useless, unnecessary, expensive to the public, and more likely to do harm than good. I am unable at present to continue my letter, but one more will conclude my observations.

Yours obediently,
E.B.

ABSORPTION OF THE MAMMÆ AND TESTES UNDER THE USE OF IODINE,

To the Editors of the *Provincial Medical and Surgical Journal*.

GENTLEMEN,—To the question proposed in the *Journal* for January 21st, relative to the absorption of the mammæ and testes under the use of iodine, I beg to refer to a case of ovarian tumour in St. Mary's Hospital, under the care of Dr. Tyler Smith, published in the *Lancet* of February 7th, 1852. At page 149 the following observations occur, bearing on the subject:—"The body of the patient gave out a strong smell of iodine; she had been using this remedy internally, and by inunction, for many weeks. There was considerable emaciation, and the *mammæ were greatly shrunk*. The nipple, which remained full and rounded, stood out as from a perfectly flat surface."

I am, Gentlemen,
Your obedient Servant,
P. GARDNER.

Southampton, February 9, 1852.

BATH AND BRISTOL BRANCH MEETING—MR. BARRETT'S CASES.

To the Editors of the *Provincial Medical and Surgical Journal*.

GENTLEMEN,—I beg the insertion of the following in correction of an error in the report of the late Branch Meeting at Bristol. It is stated that I detailed two cases which I had, during my attendance on them, diagnosed as colic, but which *post-mortem* examination showed to be internal strangulation of the ileum. What I stated was, that in the first case, at the commencement, I looked on it as colic; that when I had no doubt of the nature of the case, the general symptoms would not have warranted an operation; that in the second case, which I only saw once, I immediately, when I saw it, recognised its nature, but the circumstances of it rendered any idea of an operation perfectly out of the question.

I am, Gentlemen,
Your obedient Servant,
JOHN BARRETT, F.R.C.S.

Bath, 13, Pierrepont Street,
January 8, 1852.

[In consequence of the press of matter, the above note has been unavoidably postponed.—ED. J.]

Medical Intelligence.

HOMŒOPATHY.

At a meeting of the medical profession of Hull and the neighbourhood, held in the Library of the Hull Infirmary, January 6, 1852, Dr. Cooper in the chair; on the motion of Mr. Eddie, of Barton, seconded by Mr. Watson, of Cottingham,

It was resolved,—

"That this meeting considers that the system of treating diseases known by the name of homœopathy is entirely without foundation in theory or fact; that it is dangerous to the public health, and prejudicial to the cause of science, and that it is propagated by the combined influence of ignorance and imposture.

"That this meeting notices with much regret that the Council of the Royal College of Surgeons does not think it expedient to interfere with the practice of homœopathy by individuals holding the diploma of the College and practising with the sanction and approval which the possession of that diploma implies.

"That this meeting would respectfully submit to the Council of the College, and to the other Medical Corporations, the importance of at least making an official avowal of their condemnation of the doctrines of homœopathy, and of their conviction of the evils likely to result from its practice."

That copies of these resolutions be sent to the Secretaries of the College of Surgeons and of the Apothecaries' Company; and that the Editors of the *Provincial Medical Journal*, *Lancet*, and *Medical Times and Gazette*, be requested to insert them.

STATISTICS OF LUNATICS.

From the annual report of the Commissioners in Lunacy, just printed, it appears, on the 1st of January, 1851, there were 16,456 insane persons confined in asylums, hospitals, and licensed houses in England and Wales, of whom 7,843 were male, and 8,613 female. The total number of pauper lunatics in asylums, registered hospitals, and licensed houses on the 1st of January last was 12,059—5,592 male, and 6,567 female.

NEW MEDICAL COLLEGE.

At the annual general meeting of the Governors of the Farringdon Dispensary, held at the end of last month, Mr. Chippendale, the senior medical officer, directed attention to the New Medical College, and brought forward a plan by which institutions giving assistance to the poor might be made to contribute towards the funds of the College. He observed that the poor were debtors to an enormous extent to the medical profession, for services rendered them without fee or reward; that he, himself, had now attended at the dispensary for upwards of fifteen years, during which long period he had neither directly or indirectly reaped any advantage, either pecuniary or otherwise; that he could not, himself, accept the small contributions which might be offered by the poor, and he would say the same for his colleagues, but that we had the necessitous, the widow, and the orphan, in our own ranks, and that

it seemed but just that those who were enjoying the benefit of our labours, (for time was money,) should offer some little token of their gratitude to those of our profession who were desolate and distressed. He therefore suggested that each patient, on first coming to the dispensary, should, if a physician's or surgeon's case, give one penny, and if requiring the aid of the accoucheur, twopence; and that the sums so collected should be annually presented to the College. It might at first sight appear that such trifling amounts would not be worth the acceptance of the College; but, from calculations he had made, it would be found, that if all the hospitals and dispensaries in the kingdom would adopt the plan, enough would be raised to form a handsome endowment for the College. In such a movement it was necessary that some one institution should take the first step, and, as he was the originator of the scheme, he was anxious that the dispensary to which he was attached should have the honour of setting the example. The matter having been, duly discussed, was adopted, and ordered to be forthwith carried into effect.

LIABILITY OF EMPLOYERS FOR THE MEDICAL EXPENSES OF SERVANTS.

At the Wolverhampton County Court Mr. Kempson, a surgeon, sued Frederick Woodhall, a miner in the employ of Lord Ward, for £33. 18s., being his charge for amputating defendant's leg, for attendance; and medicine. Defendant pleaded *non debet*, inasmuch as he was in Lord Ward's employ at the time of the accident, and that, therefore, his Lordship was bound to pay the bill. Mr. Smith, agent to Lord Ward, argued, *e contra*, that his Lordship was not responsible, because, at the time of the accident, the man was not engaged in the mine, but was riding a cart over ground when, by his own carelessness, he fell under the cart, and sustained the injuries. The learned Judge, Mr. Sergeant Clark, adjourned the case, in the hope that the matter might be amicably arranged. It is but fair to add that but one feeling pervaded the court—that Lord Ward was morally bound to pay the bill.

KING'S COLLEGE HOSPITAL.

According to the plans and specifications of the proposed additions to King's College Hospital, the new buildings will cover the whole of the Green Yard Burial Ground, and also the site of the houses lately pulled down in Carey Street. The excavations for the foundations will be made very deep, in order that the bodies in the grave-yard may be removed to a suburban cemetery. It is unnecessary to add that so dense and so populous a neighbourhood demands an hospital of very large extent.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on Friday, the 6th instant:—Wyndham F. Armstrong, Adare, Co. Limerick; Robert Elliott, Tyrone; Henry Ellis, Bangor, Carnarvonshire; John Gabriel French, Jewin Street, Aldersgate Street; Henry Gramshaw, Gravesend; John Henry Hewer, Chobham, Surrey;

Peter Nevill Jackson, Beverley, Yorkshire; Richard Pery, Dublin; Ridley Porter, Bishopsgate Street; Clement Sconce, Bath; David Swining, Winslow, Bucks.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, Jan. 29, 1852:—Frederick Ward Cleeve, Bradnich, Devon; Thomas Edward Halls, Broad Street, Horsleydown; Henry Simpson, Chester.

Gentlemen admitted on Thursday, Feb. 5, 1852:—Alfred Ball, Brighton; Charles Chibnall, London; Mark Kebbell, Brighton; John Lacey, Brighton; William Tidboald Luxton, Winkligh, Devon; John Bidlake Mountford, Exeter.

OBITUARY.

On the 30th ult., at Bicester, Oxfordshire, after a few days' illness, Edward Hugh Thorpe, Esq., surgeon, aged 38.

Feb. 3rd, at Frankfort-on-the-Maine, Sir Alexander Mackenzie Downie, M.D., aged 41 years.

On the 25th of June last, at Spring Bay, Hobart Town, aged 39, W. Morgan Underwood, M.D., sixth son of the late Rev. Thomas Underwood, Rector of Ross and canon residentiary of Hereford Cathedral.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE.

THE COUNCIL OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION hereby offer a PRIZE OF TWENTY GUINEAS for the best *Series of Reports of Medical Cases* that may occur in any of the Provincial Hospitals, which shall be sent to the *Provincial Medical and Surgical Journal* for publication, between the FIRST OF OCTOBER 1851, and the FIRST OF OCTOBER, 1852.

THE COUNCIL also offer a PRIZE OF TWENTY GUINEAS for the best *Series of Reports of Surgical Cases* that may occur in any of the Provincial Hospitals, which shall be sent to the *Provincial Medical and Surgical Journal* for publication, between the FIRST OF OCTOBER, 1851, and the FIRST OF OCTOBER, 1852.

House-Surgeons and Pupils of the Provincial Hospitals to be eligible candidates for the Prizes.

NOTICE TO MEMBERS.

Members who wish to propose Associates are reminded, that as the subscription commenced on the first of January, it is the most convenient time to introduce new Associates.

It is also particularly requested that all post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

JAMES P. SHEPPARD, Secretary.

Worcester, January, 1852.

TO CORRESPONDENTS.

Communications have been received from Observer, Dr. Dickenson, Scrutator, Mr. Ikin, Dr. Hall, Mr. Hughes, Dr. Oke, Mr. Postgate, Mr. Barrett, Mr. Foote (twice).

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

MEDICAL BENEVOLENT COLLEGE.

ESTABLISHED JUNE, 1851.

PRESIDENT.

THE EARL MANVERS.

TRUSTEES.

DR. J. A. WILSON.

DR. R. LEE, F.R.S.

W. FERGUSSON, Esq., F.R.S.

JOHN BACOT, Esq.

BENJAMIN PHILLIPS, Esq., F.R.S.

TREASURER.

JOHN PROPERT, Esq., 6, New Cavendish Street.

THE COUNCIL have much satisfaction in being able to publish, thus early, the SECOND LIST of Contributors to the Funds of the College, and they are induced to hope that, as the principles and objects of the Institution become better known, it will receive the unanimous and cordial support of the entire profession.

Subjoined is a list of gentlemen who have kindly consented to act as Honorary Local Secretaries for their respective neighbourhoods:—

HONORARY LOCAL SECRETARIES.

Allison, W. Esq., East Retford, Notts
Barker, J., Esq., M.D., Richmond
Barker, T. H., Esq., M.D., Bedford
Barnett, J. H., Esq., Farringdon
Bayntun, Wilmot R., Esq., Bath
Beaumont, John, Esq., Cheshunt
Bleack, C., Esq., Warminster
Bowling, J., Esq., Hammersmith
Bumpstead, T. B., Esq., Cambridge
Bunce, J. S., Esq., M.D., Woodford
Burrows, J. Cordy, Esq., Brighton
Bury, G., Esq., Whetstone
Carr, W., Esq., Lea
Clifton, Nat. H., Esq., Islington
Coates, W. Martin, Esq., Salisbury
Collambell, C., Esq., Lambeth
Colthurst, J., Esq., Clifton
Cooper, G. Esq., Brentford
Copeman, E., Esq., Treasurer, Norwich
Cotton, C., Esq., M.D., Lynn, Norfolk
Cribb, H., Esq., Bishops Stortford
Cripps, E., Esq., Cirencester
Curtis, G., Esq., Dorking
Curtis, H. C., Esq., Great Marlow
Cutfield, A. B., Esq., Deal
Davis, W. G., Esq., Heytesbury
Day, Horatio, Esq., Isleworth
Dickenson, J., M.D., Liverpool
Drage, C., Esq., Hatfield
Eastes, Silvester, Esq., Folkestone
Elliot, R., Esq., M.D., Carlisle
Elliott, Wm., M.D., Stratford
Ewen, H., Esq., Long Sutton

Fisher, W. P., Esq., Dartford
Fox, L. O., Esq., Broughton, Stockbridge
George, E., Esq., M.D., Sandgate
Gill, G. P. B., Esq., Shrewsbury
Godrich, F., Esq., Brompton
Gorham, J., Esq., Tunbridge
Gorham, R. V., Esq., Aldeburgh Suffolk
Gruggen, H. M., Esq., M.D., Chichester
Hammond, T. M., Esq., Brixton
Harper, P., Esq., Bilston
Harris, W., Esq., Worthing
Harrison, G. F. B., Esq., Devonport
Haviland, Alfred, Esq., Bridgwater
Hawthorne, A. N., Esq., Eccleshall
Hester, J. Torry, Esq., Oxford
Hilliard, W. H., Esq., Shefford, Beds
Hillier, H. B. C., Esq., M.D., Tenby
Hoffmeister, W. C., Esq., Cowes
Inman, R., Esq., Preston
Jones, A., Esq., Epsom
Johnson, J. G., Esq., Norwich
Kennion, G. Esq., M.D., Harrogate
King, Osmer, Esq., Greenwich
Lawford, E., Esq., Leighton Buzzard
Leithead, T., Esq., Warkworth
Lomax, H., Esq., Stafford
Martin, A., Esq., M.D., Rochester
Martin, P., Esq., Reigate
Morris, E., Esq., M.D., Spalding

Morris, T., Esq., Peckham
May, G. P., M.D., Maldon
Paley, W., M.D., Peterborough
Pemberton, Oliver, Esq., Birmingham
Phenè, H., Esq., Rhyde, Isle of Wight
Phillips, J., Esq., Bethnal Green
Pinching, C. J., Esq., Gravesend
Power, J. J., Esq., M.D., Maidstone
Poyser, T., Esq., Wirksworth
Pratt, Spencer, M.D., Stamford
Prichard, J., Esq., Leamington
Pyle, C., Esq., Amesbury
Ray, G. Esq., Milton, Sittingbourne, Kent
Robertson, J., M.D., Hitchin, Herts
Sankey, W., Esq., Dover
Smith, C. C., Esq., Bury St. Edmunds
Smith, W., Esq., M.D., Weymouth
Smyth, Spencer, T., Yarmouth
Stedman, J., Esq., Guildford
Stevens, J. N., Esq., Plymouth
Sterry, H., Esq., Bermondsey
Stilwell, G., Esq., Epsom
Stowe, W., Esq., Buckingham
Sweeting, W., Esq., Dorchester
Turner, R., Esq., Tunbridge Wells
Vines, C., Esq., Reading
Walter, J., Esq., Dover
Ward, T., Esq., Watford
Worthington, W. C., Esq., Suffolk
Whitshed, J., M.D., Wisbeach
Young, D. S., Esq., Boulogne
Young, F. A., Esq., Hawkhurst

LECTURE
ON THE
DISEASES OF CHILDREN.

DELIVERED IN THE

Chatham Street School of Medicine, Manchester,

By DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesh, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesh; Fellow of the Imperial Society of Medicine at Vienna, etc.

LECTURE VIII.

Children's therapeutics in general. The remedies for the first weeks after birth; quantities to be prescribed at once; when to abstain from medicine. Direct antiphlogistics—bleeding, cold water, cooling prescriptions. Purgatives—the aromatic senna tea.

GENTLEMEN,—

The tenderness of the organization of children, their system being so easily deranged by inconvenient qualities and quantities of medicines, and on the other hand, the important fact, of which I have been satisfied by a large amount of comparative cases—viz., that children's diseases, though in general more fatal than those of adults, end in recovery in their great majority by the activity of nature alone, if the dietetic and hygienic circumstances be suitable to the case, these considerations, I say, ought to induce the practitioner, in particular the young one—

1st. To abstain from active remedies in cases not very clear to him.

2nd. To maintain in general a great simplicity, and moderate quantities in his prescriptions.

Certainly, acute diseases of children, especially of the inflammatory kind, should be met by a quicker decision on the side of the physician, and much more energy in the application of remedies than in the case of adult patients; but as medical practice is but an art of approximative truth, and of relative results, I am satisfied, that the practitioner who, in cases ambiguous to his understanding, abstains from active treatment, will have in his favour a better proportion of success than one who goes on in the opposite line.

With regard to remedies for the *first few weeks after birth*, there are but few suitable and safe. *Cold water*, with a little sugar, as a frequently repeated drink, is the best and the most active, cooling, antiphlogistic medicine for this age, which, if not effective enough, I know further for that purpose only cold fomentations and leeches; other remedies of the kind, such as calomel, neutral salts, and acids, being decidedly improper for an organism so delicate and sensitive. Then, for other indications, castor oil, small doses of hot infusions of camomile, mint, fennel seeds, a few doses of a stimulating tincture, or a quarter of a drop of tincture of opium. Besides these, different fomentations, poultices, ointments, and injections, constitute almost the whole apparatus to which I limited my practice in this early

period of life. Blisters and sinapisms, if requisite, must be applied in a six-fold weakened state, mixing the one with simple plaster and the other with linseed powder. Syrups and emulsions I have entirely ceased to employ at this age. They are inactive, heavy to the stomach, easily derange the digestion of the breast milk, and promote acid fermentation and flatulence; whilst, on the other hand, the milk of the breast itself possesses an excellent soothing quality for the inflammatory affections of infants, in particular those of the throat and bronchi.

Powders are in general improper for the first month or two, and insoluble ones—like calomel, the most objectionable. I have been satisfied that calomel easily causes erosions of the mucous membrane of the stomach of tender infants. I cannot conceive why and how any practitioner could prescribe calomel for the purpose of expelling the meconium. Is not castor oil evidently the most suitable for it? Salts, acids, and mucilaginous or astringent decoctions, either by their quality or relative bulk, are liable to produce gastric derangement, which it is very important to avoid in infants. Subsequent to the second month, there is already much more tolerance of remedies; and in the second year, when the child's stomach has become accustomed to substantial food, there is already a field for a variety of powerful drugs, if they are truly indicated and properly administered. But, supposing even the most skilful practitioner—one able to fix upon the time and indication, even for him it ought to be a general rule to prescribe small quantities in children's practice. One reason for this lies in the unaccountable rapidity of changes in their maladies; the other is the extreme delicacy and manifold idiosyncracies of their stomach and nervous system; and one reason more, our own professional credit, because it always makes a better impression to repeat the same prescription, if necessary, the same day, than to write another whilst the former is not yet consumed, and to cause in this way, at the bed-side, an accumulation of half-emptied medicine bottles and powder-boxes.

I am sorry to say you will find medical practice more arduous than we found it when I commenced the study; your credit will be placed in greater difficulty, and be more easily lost; a great revolution in the human spirit has taken place; and whilst absolute authority in science, and blind faith in our practice have become lessened very much, you will require more of scientific information, and much more accuracy and attention in the exercise of the art than your predecessors did.

I beg your pardon in making these remarks, which I merely regard as a digression; but I entreat you, do not forget, that even one teaspoonful given every hour or two hours, of a dense liquid, with taste and smell very heterogeneous to the organs of a child, is a large quantity, and liable to add a new disorder to that which you wish to cure. It is a fact that infants and children are frequently over-drugged, and their speechless complaints arising therefrom are easily overlooked. The public are aware of this.

I recommend to you the following proportion for

liquids :—For a child less than six months old no more than one ounce, as a single prescription. For a child about two years old no more than two ounces. These quantities you may regard in general as sufficient for one day. With powders you must act upon the same principle; in acute cases *never prescribe more than sufficient for one day*. I feel anxious to direct your attention to this point in children's practice, because you will find even in modern works of great value for the student's information, (as, for instance, that of Professor Churchill, of Dublin,) prescriptions of too large a supply. You will find, for instance, a solution of tartar emetic in four ounces of almond emulsion, one teaspoonful every three hours, consequently enough for at least four days, whilst (besides the possibly earlier change in the disease) the emulsion will always become spoiled, decomposed, and non-applicable, by the end of the second day. You will meet there, with the prescription of other mixtures, of a powerful character, containing ammonia, ordered in acute and severe cases, of children under two years of age, to the amount of four ounces, and more, to be administered by teaspoonful doses, at three or four hours' interval. I have nothing to say of the indication, and find the prudence of so distinguished a physician worthy to be imitated by yourselves—viz., to order of similar remedies only by teaspoonfuls every three or four hours; in this way you will be able to watch its effects upon your delicate patient, and do away with it in case that you find them unfavourable, before mischief could have been produced. But, one teaspoonful at similar intervals will hardly amount to one fourth part of the whole alluded to in twenty-four hours, during which interval you will certainly repeat your call, in the case of an acute malady, so subjected to sudden and unaccountable changes. I think there is no physician, however clever he may be, who can exactly know what may happen the next day with an acute malady of a child, consequently why should you expose yourself unnecessarily to the accumulation of half-consumed drugs. This you must avoid, because it is almost disgusting to look upon these remains at the bed-side, and it is not seldom unfavourable to the credit of a young practitioner amongst the enlightened classes. It is sufficient if you prescribe in acute cases, just as much as you think enough for twenty-four hours. And even these small quantities we are frequently obliged to discontinue after a few doses. The causes of discontinuance are by far more numerous with children than with adult patients. There are plenty of idiosyncracies with them unexpected and unaccountable. The child cannot complain; so much the more attentively must you follow the effects of your medicine, and suspend or part with it, according to circumstances. It happens then not unfrequently that your next prescription will be still less supported, and you incline to supply a third. Be cautious with these cases where your indications are repeatedly delusive. If there is not the most evident urgency for another prescription, I advise you to wait a certain time, and observe the little patient when freed from medicinal impressions. This conduct be-

comes almost an imperative rule, if you have observed that your former prescriptions caused a long-lasting uneasiness or gastric disturbance to the child. There is a certain system of—you know what I mean, which, after repeated, overhurried, and overwhelming medicinal attempts, in many cases gets the patient better by doing nothing, confiding in hygiene and Nature's power, and then praising the cure as their own work. It is useless, if not altogether inconvenient, to attack such a system directly and violently. Let us improve in science, and be more correct in the exercise of our art; in this way, and perhaps only in this way, we may prevent or check the growth of parasites in medicine.

I will now proceed to communicate to you my experience and views upon the most useful, and almost the only necessary remedies for the diseases of children. Some of them, as you will find, are more or less extraneous to the English pharmacies, but by the kindness of an eminent pharmacist of this town, (Mr. Robertson, Oxford Street,) who partly prepared them in his chemical laboratory, and partly procured them from Hamburg, I shall be able to show you several specimens, some of which I have brought with me to day. But let us proceed with a certain order, and speak before all of the direct antiphlogistics.

Bleeding, as you know, is the most powerful of this class; and venesection is the kind of bleeding which, in childhood as well as in other ages, is decidedly indicated against acute inflammation of parenchymatous organs; but it is very improper to bleed with the lancet, if there is no vein of sufficient dimension. The very indication of venesection supposes a free flow from the wound, which I have been satisfied is seldom attainable in children under five or six years of age. In similar cases, instead of harassing the child by long and ineffective attempts at the operation, I am accustomed to supplant this kind of bleeding by a proportionally large number of fine leeches, to be applied all at once, exactly along and upon the clavicles, detaching them altogether, as soon as a sufficient quantity of blood has been obtained, and stopping immediately with efficacious means the hæmorrhage. In this way we approach the sudden and strong effects of venesection much better than cutting a vein, which gives the blood only drop by drop.

With regard to the general purpose of local abstraction of blood, we may consider it as a rule to leech a tender infant with small leeches, and to use larger ones in proportion to the age. It would be impossible to express an exact quantitative scale of leeches; their number must be proportioned not only to the age and malady, but should vary according to a great many other circumstances. If you would ask me, however, some points of an approximate scale, then supposing the child to be of a good constitution, and allowing the bites of the leeches to bleed for half an hour, I would regard the following gradation as answering the purpose of an energetic bleeding :—

In the	1st month	2 leeches, small ones.
"	2nd "	3 " "
"	4th "	4 " of middle size.

In the	8th month	6	leeches of middle size
"	12th "	8	" "
"	16th "	10	" "
"	2 years	12	" "
"	3 "	14	" "
"	5 "	16	" "
"	8 "	18	" "

These, I repeat, are powerful quantities of blood, only applicable in the first stage of the most acute and extensive inflammation in a healthy and strong constitution.

The *counterindication* of bleeding is of higher importance with children than grown-up patients. A few leeches, by a mistaken indication, can, in the latter, produce a disastrous effect. Guard against leeching a chlorotic, atrophied, or rachitic child; these are the most decided counterindications, and you must be a good observer, in order to detect these counterindicative complexions, even in a moderate degree, to avoid hurtful mistakes; for instance, by leeching the head of a rachitic child, on account of repeated headaches, to which they incline, or the chest, because it coughs, with simultaneous dyspnoea, the result of its narrowed chest. For ambiguous cases accept the rule, that it is better to let an inflammation, which would be very much benefited by leeching, run its course without it, than to leech in a case which is not inflammatory, in a rachitic or in an anæmic child.

Cold water.—I had already opportunity to recommend it as the unique antiphlogistic remedy, to be taken by mouth, for suckling infants. As much as one or two dessert spoonfuls every hour, may be considered as effective quantities for children one or two years' old. Of the external application of cold water, I shall speak amongst the external remedies.

Very frequently we meet, amongst the antiphlogistic apparatus, emulsions, (sometimes strengthened with a solution of nitrate of potass,) acids, and neutral salts. All these prescriptions I find objectionable for infants or tender children. If we continue to give them for one day or two, the stomach of these delicate creatures commonly becomes deranged. Of mercury I will speak in another place. There are, however, cases of children already past the age of lactation, in which some circumstances invite you very much to prescribe a cooling medicine. No doubt cold water is not so active with them as in suckling children; and, on the other hand, their stomach bears already some heterogeneous impressions. Then let me recommend to you for such the following *cooling mixtures*:—℞. Aquæ Destillate, ʒ j.; Kali Citrat., ʒ ss.; Syrup. Citr., ʒ iss. For a child about one year old, every hour or two one teaspoonful. Or, if there is a fever, characterised by the high temperature and dryness of the skin, with a tendency to a pharyngeal inflammation, the following is worthy your confidence:—℞. Decoct. Fruct. Tamarind. (ex, ʒ ij—iij.; ad Aquæ ʒ iss.) Acid. Hydrochlor. Dilut., ʒ j.; Syrup. Citr., ʒ iij.

Purgatives.—To void, if necessary, the meconium, and in general for tender infancy there is but one convenient purgative, that is, castor oil. After the fourth month, if a stronger purgative is wanted, I have

found the following preparation to answer the best, of which I show you here in this bottle, under the name of *aromatic senna tea*, prepared by Mr. Robertson, as follows:—

A quantity of Alexandrian senna leaves are digested with proof spirits of wine during twenty-four hours, then taken out, moderately squeezed, and then slowly dried by moderate heat. Then take of the—

Prepared senna leaves	4 parts
Camomile flowers	1 "
Elder flowers	1 "
Fennel seeds	1 "
Anis seeds	1 "

Of this mixture the quantity adequate for a child about six months old will be for one infusion, dose ʒ j.; for a child two years old ʒ ss. or ʒ ij.; for an adult about ʒ ij.—iij. To each portion you may add bitartrate of potass in the proportion of gr. xij to ʒ j. of the tea. At the time, when needed, a hot infusion is to be made, during fifteen or twenty minutes, with a quantity of water not larger than the patient is able to take at once, sweetening it with a little sugar. The action is generally exerted after about three or four hours; if not at that time, then the same dose must be repeated.

With regard to the camomile and elder flowers, entering in the above composition, I must observe that I use the samples of these aromatics imported (by the care of Mr. Robertson) from Hamburg. All aromatics of the English soil are considerably less strong than those of the Continent. The English camomile, as everybody can be satisfied by comparison, is very different from that of Germany, the former being much more bitter, and much less aromatic; consequently the English makes the infusion disagreeable and less antispasmodic. The difference of climate, in particular the dry hot summer of Germany, as well as of the southern countries of Europe, account for this difference.

From this aromatic senna-infusion, I can assure you, you will derive great benefit with delicate children as well as ladies. Its aromatic ingredients obviate, in general, griping, and promote the expulsion of flatulencies. For a child above six months old, and of a good complexion, if you desire a strong derivative effect of the purgative, you may use the common senna-infusion with some neutral salt dissolved in it. In some cases jalap with calomel. This latter, however, I object to very strongly as a simple purgative; it is in its place if we wish to act upon the excretion of the bile.

Next we will proceed further in the series of remedies.

CASE OF

FRACTURE OF THE SPINOUS PROCESSES OF THE LUMBAR VERTEBRÆ.

REMARKS ON THE TREATMENT OF SPRAINED BACK BY "FIRING."

By JAMES DICKINSON, Esq.

AMONG the various, I may say numerous, accidents, which are continually occurring in the iron works, none perhaps are so frequent in occurrence as injuries to the

spine; nor need this surprise us if we consider for a moment the class of men to whom these accidents happen, viz., miners and colliers, who work in small compartments, technically termed "stalls," the roofs of which are so low as to compel the men, while working, to stoop forward, and at times to sit, so that if any of the superincumbent mass give way, it is almost certain to fall on their backs. These pieces of mine vary in weight from a few pounds up to a ton. In no case but in the one reported below have I met with fracture, nor, I may add, any unfavourable symptoms. Retention of urine, generally spoken of as being so common, has not occurred in a single instance. The men complain of some stiffness, but are generally able to resume their work in a few days.

At eight A.M., I was sent for to see J. M., a collier, who stated that about one o'clock that morning a lump of mine weighing upwards of half a ton had fallen on his back. On examination I found great effusion in the lumbar region, circumscribed, having the appearance of a cyst to the touch; it was soft and yielding, giving one the idea of a bladder filled with water. On feeling for the extremities of the spinous processes, all traces of them were lost from the first to the fourth lumbar vertebræ or thereabouts. This abnormal appearance, I was inclined to attribute at the time to the effusion, which prevented a perfect examination. The part was ordered to be constantly fomented, determining to check if possible, any unfavourable symptoms that might arise. The accident occurred on the 10th of May, and he was visited daily up to the

24th.—No symptoms having arisen demanding interference, all swelling having now subsided, I was enabled to examine more accurately the spine, when my previous diagnosis was fully confirmed. From the first to the fourth lumbar vertebræ inclusive, in a line corresponding to the extremities of the spinous processes, all traces of them were lost, and in their places was a soft yielding surface; the outline of one of the spines, however, I fancied I could detect, deflected to one side. The last dorsal and lumbar spines could be distinctly felt. He never lost sensation and power over his legs, and only complained of weakness in his back. The man improved daily, and six weeks from the date of the accident resumed his work.

Remarks.—Mr. Shaw accounts for the absence of unfavourable symptoms in these cases, by stating "that from the tenth dorsal vertebra, where the cauda equina commences, to the termination of the spinal cord at the second lumbar vertebra, the roots of the nerves enclose and protect that important organ so effectually, that severe injury to the surrounding bones may not reach the cord. When fracture occurs lower down, of course the dangers of paralysis taking place are diminished, for the long loose nervous fibres composing that part can accommodate themselves to the changed direction of the canal, without loss of function." He also points out the fact of "the lumbar vertebræ having to sustain the greatest weight of all the spine, as well as enjoying considerable freedom of motion, and accordingly liable to sudden and severe shocks, it was provided that the

spinal marrow should close this up, in order to protect it from injury." The case is interesting, as affording an illustration of Mr. Shaw's views, as well as pointing out the fact, that in these cases we are enabled to give a more favourable prognosis, and speak with greater certainty, than in injuries situated higher up.

"*Sprained backs*" are cases which give the surgeon, both in private and public practice, much trouble and annoyance, appearing, as they do in many cases, to resist every remedy. Many cases having come under my notice, and finding that blisters, cupping, stimulating liniments, &c., failed, at the suggestion of Mr. Hinton, I tried "firing," and the results have been most successful: patients who for many weeks have evinced the greatest agony, have, after the first or second application, been perfectly cured. The plan to be adopted is as follows:—Heat a small metal button, (the shank of which is fixed in a wooden handle,) over a spirit lamp to such a temperature as can be borne with slight pain, then pass it several times lightly over the part referred to, and which, in most cases, is confined to a particular spot on the back. It is unnecessary to produce vesication, a slight redness of the skin sufficing. A second application is not often required; a third seldom, if ever. The pain, I would observe, produced by the application appears to be rather severe, and causes them to jump, the effect produced being not unlike that of galvanism; it is, however, quite transient, passing off in a few minutes. Of the beneficial results of this remedy the following case will afford an example:—

An old man had been suffering from a sprained back for seven weeks; he was unable to follow any employment, from the constant pain, aggravated as it was by the slightest motion. I well recollect seeing him walking to the surgery, at a very slow pace, with the aid of two sticks, and his body bent forward, and also the change that resulted from the "firing." He felt much easier, was enabled to walk home at a moderate pace, and carried himself more upright. Two more applications were necessary. At the end of ten days he was quite free from all pain.

It is in such long-standing cases as this, that two or three applications are required; in recent cases one will be found sufficient. That there is nothing novel in the plan of treatment I am well aware; that it has from time to time been recommended is no less true: nevertheless, it appears to me to be a remedy which has fallen into desuetude; I have, therefore, brought it before the notice of my professional brethren with the hopes that they may be induced to employ it. The easy mode of application, the certainty of its results, and the rapidity with which it gives relief to the patient, (in many cases in a few hours), are points which, in my opinion, more than counterbalance the chronic plan of treatment, (if I may use the term), by which a patient becomes incapacitated as much from the severe cupping, blistering, and counter-irritation, in its various forms, as by the original sprain. Ought we, then, I ask, to discard a remedy so simple and unfailing?

Blaina, February 6, 1852.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CASES

Reported under the Terms proposed by the Association.

BY SCRUTATOR.

Injuries of the Head.

JAMES HACKNETT, aged 14, was admitted into the Queen's Hospital, July 21st, 1850, and his friends gave the following history of his case:—Just one week before he had received a kick from a horse on the back part of the head, about an inch to the left of the occipital protuberance. The immediate effect of this blow seems to have been concussion, as the friends state he was "stunned," and shivered much during the time which elapsed before he could be taken home. He also vomited. He was during the day seen by a medical man, who prescribed castor oil, and eventually bled, leeches, and blistered him. These means succeeded, in a great measure, and the boy appeared to have been progressing favourably, when symptoms of excitement supervened, and his friends brought him to the hospital, in consequence, as they stated, of not being able to manage him, particularly in the night time.

On admission there was observed to be a certain wildness of manner, combined with fear, which gave the lad the appearance of idiotcy; he, however, knew his friends, and said he was brought to the hospital, but was stated to have forgotten everything relative to his accident, and would not answer any question put to him. The pupils were dilated, and the pulse counted 90, having some force and roundness. He did not complain of pain, and there was no tumour or other indication of the blow present, although it was stated that at first there was a large swelling in such situation.

When taken into the ward he remained tolerably quiet for some time, but towards evening he became restless, wished to go home, and implored the nurse and others not to harm him, putting his hand to his head, and complaining of pain there. The bowels not being open, he was ordered to take a dose of calomel and croton oil, which operated powerfully. During the night he was very restless, shouting, and endeavouring to get out of bed at times, saying he must go to work, or should lose his situation. Towards morning he fell asleep.

22nd.—This morning he is much more quiet, but restless; pupils much dilated; some heat of scalp; pulse about 90. He will not answer questions, but implores to be allowed to go to work, and complains that some one has stolen his clothes. His manner altogether is very peculiar, and he has a very anxious look. He calls the nurse "Annie," Mr. Cox "gaffer," and the House-Surgeon "Tom," his mind evidently being confused by recollection of his friends and his present

situation among strangers. Ap. Cucurbitulæ ad oz. viij. nuchæ postea Emp. Lyttæ. Hab. Cal., gr. ij., tertiis horis.

23rd.—After the cupping he appeared relieved, and again went to sleep for a time; during the remainder of the day he was very restless, and on one occasion darted out of the ward and through the hospital into the street, before any one could stop him. The night had been passed on the whole more tranquilly than before, but he had occasionally been very violent, requiring force to restrain him. His pulse this morning counts 96, and the pupils still dilated, and he at times complains of acute pain in his head. Cont. Cal.

24th.—Has been more quiet during the night, and to day has the appearance of a person much fatigued, it appearing a trouble to him to move or turn. The calomel has affected his mouth, and the pupils are less dilated, but still very large. Pulse counts 100, weak. Cont. Pulv. Calom., ter in die. Rept. Emp. Lyttæ nuchæ.

27th.—Not much change; he does not now attempt to get up, but moans occasionally. To have better diet. To take no medicine.

30th.—Has improved the last three days, and now sits up, and begins to join in conversation with those around him. He relishes his food, but still has a peculiar wildness in his looks and manner.

August 8th.—Since last report he has been progressing favourably, and is now well. He has lost the wildness of manner, and the pupils have become natural. He can go on an errand well, and does not remember the accident, or anything for some days after. He was discharged August 11th, and has since that time remained perfectly well.

HENRY STANLEY, aged 14, was admitted Jan. 24th, under Mr. Sands Cox. Some time before admission he had received a kick from a horse on the head, and was brought to the hospital in a state of insensibility. The body generally was cold; the pupils moderately contracted, and the eyelids half closed; the face pale and pulse feeble and intermittent. There was a swelling about the centre of the right parietal bone, and also a slight abrasion on the hip. Warmth was applied to the feet, and quietude enjoined. In the course of the afternoon he became sensible, and complained of pain of the head, and general uneasiness. A dose of calomel, followed by castor oil, was administered, and cold applied to the head. He had no other symptoms, and was discharged two days afterwards well.

CHRISTOPHER ARCHER, aged 16, admitted February 13th, under Mr. Sands Cox. Was found insensible at the bottom of some cellar steps, which it was inferred he had fallen down. When admitted into the hospital he was still insensible, but could be partially roused. The pulse was weak and intermittent; the pupils contracted; body cold, and breathing of a sighing character. Warmth was applied to the feet, and the boy became perfectly sensible and collected in the course of a few hours

14th.—He complained to day of some headache; pulse small, and intermits occasionally; pupils act well, and there is no heat of scalp; bowels not moved. Hab. statim, gr. v.; Calom. et postea. Mist. Purgant., oz. ij.

15th.—Bowels have been well moved, but the boy to-day seems frightened, and wishes for his relations. Complains of pain in the head, but is tractable. He does not, however, notice anything that passes around him. Pulse weak, intermitting occasionally. No particular heat of scalp. Ap. Hirudines xx. Capiti raso. Rept. Calom. et Mist. Purgans.

16th.—About the same in all respects.

17th.—During the night has been very violent, wishing to get up and go out, and fearing some imaginary person was about doing him some injury; he was, however tractable, and easily induced to lie down again. Pulse counts 100, and has more force than yesterday. Pupils slightly contracted, and head rather hot. Ap. Hirudines viij., temporibus. Hab. Calom., gr. ij. Tertiis horis.

18th.—Was much quieter during the night and slept a little. In most respects he seems about the same, but says he is quite well and wishes to go home. Continue calomel.

19th.—Has been quiet during the night, and seems much better this morning. The calomel has slightly affected his gums, but he has no pain or uneasiness in any part, and the pupils act well. Pulse is moderate. He continued to improve and eventually left the hospital, March 1st, being then quite strong and well.

It has often been observed that there is no other part of the body which, being affected with disease, gives rise to such anomalous symptoms as the head, thus rendering the diagnosis at once uncertain and difficult, and requiring the utmost amount of discrimination to approximate to a correct conclusion regarding the existing state of affairs; and this difficulty is moreover increased because we cannot explore the interior by manipulation, or by the exercise of any special sense, as we are enabled to do in other parts of the body. As in disease, so are these difficulties equally felt by the surgeon when called upon to treat injuries of the head, and there oftentimes will be sound symptoms of a dangerous nature, following perhaps a minor injury, while what appears of greater moment gives rise to little or no disturbance. (Case 2.)

The variety of symptoms observed after concussion are very remarkable, and can scarcely be explained on any principles with which we are acquainted. Sometimes we find a patient really without the slightest ill effect, scarcely feeling any headache afterwards, while another seemingly affected primarily in the same way, lies in a half conscious state for some days, (Case 3,) or becomes delirious, or dies comatose. Some, again, agree in many respects with that peculiar state which Mr. Fravers has designated as prostration with excitement. Sometimes, however, and this was verified in Cases 1 and 3, symptoms are observed much resembling those of delirium tremens; often the symptoms will be found

to correspond very minutely; thus, although the patient is violent he will easily be prevailed upon to lie down, and will often answer rationally for a moment or two. Besides this, it is generally of his affairs that he talks, wishes to go to work, and continually asserts that he is in health. He is also afraid of strangers, and considers every one mistrustfully, thus making the analogy between the two states still stronger.* Occasionally, also, the patient recovers in all respects except one; the hearing may be deficient or not so acute as before the accident, the taste may be perverted, the names of places may have been forgotten, or the patient may be affected in various ways or quite lost, as lately happened in a case under Mr. Sands Cox. As regards the treatment of these cases it seems to be of the utmost importance to preserve a strict quietude during the critical period of reaction, for in that state a little thing will determine the balance; and a patient, who is subjected to noise, light, or other annoyances, will not be so likely to progress favourably as one equally injured who is kept free from these excitants, therefore too much importance cannot be well attached to this point. The treatment, moreover, laid down by Mr. Guthrie, in his work on "Injuries of the Head," is fully adequate to the desired end.

Severe Laceration of the Scalp; Erysipelas; Recovery.

RICHARD WILKINS, aged 36, was admitted into the hospital, under Mr. Sands Cox, January 2nd. He had, some hours before admission, fallen from a cart, the wheel of the vehicle causing a scalp wound, which extended nearly from ear to ear, slightly behind the coronal line. The scalp could be turned back for some distance, and the pericranium was in one or two places detached from the bone. The wound was filled with grit and dirt, which was, as much as possible, removed, a syringe, sponge, &c., being used. The parts were then brought into apposition, and sticking plaster and a bandage applied. He was stated to have been slightly in liquor at the time when the accident happened, and appeared, from what was related, to have suffered from concussion; but when he was brought to the hospital the pulse had regained its frequency and force, and there was nothing particular observed.—Hab. nocte Cal., gr. v. cap. Mist. Purg., oz. ij.

January 3rd.—Going on well; makes no complaint; bowels well opened.

4th.—Complained yesterday evening of shivering, and this morning has pain of head, with general feverishness, pulse counting 100. The wound was dressed, but union had not taken place, and its aspect was such as to require poulticing, in place of other dressing.—Rept. Pulv. Cal. et Mist. Purg.—R. Ant. Pot. Tart., gr. j.; Mag. Sulph., oz. v.; Misce, sumat oz. j., quartis horis.

5th.—Bowels have been well moved, and he feels better to-day. Wound has begun to discharge; pulse

* See Copeland's Pract. Med. Dict.

counts 90; there is but little pain of head, and he makes no complaint. Cont. Mist.

6th.—Wound about the same; bowels open. The back part of the scalp over the parietal and occipital bones is puffy and tender. Pulse counts 100. Has wandered slightly during the night. Cont. Mist. To go on with the poultice.

7th.—An incision was to-day made into the swelling on the occiput, which gave exit to a large quantity of pus. He expresses himself as feeling better. Old wound discharges more. Cont. Mist.

8th.—To-day a large portion of the occipito-frontalis tendon was removed in a sloughing state from the wound. He appears very weak, but has no pain. Bowels open. To have half a pint of porter daily, and meat diet.

9th.—Wounds are now granulating, and discharge but little. In all respects better. To be dressed with plaster, &c..

11th.—Going on well. Full diet.

He continued from this date gradually going on well. The wound was dressed daily, and compresses placed at different parts to expedite the union of the scalp and periosteum. It was not, however, until February 27th that he was discharged, on which date the head was quite well.

It is an old maxim in surgery that no injury of the head, however trivial, should be neglected; and this applies equally to the external as to the internal parts. Wounds of the scalp are very likely to be followed by erysipelatous inflammation and formation of matter, which, if not checked by energetic treatment, will probably terminate in necrosis of the bone, and render the case not only dangerous, but tedious and troublesome in the extreme. Also, in consequence of the free communication between the vessels of the external parts and those of the dura mater, inflammation is very likely to pass internally, and thus further complicate the case. Owing also to the loose cellular tissue beneath the scalp, the matter will burrow, raising the integuments, and giving the head a swollen and unnatural appearance, as happened in the case related. This state of things can only be combatted by energetic treatment. Antiphlogistics must be used, and in many cases blood extracted, while free incisions must be made for the exit of any pus which may have formed. Frequently, as in the case reported, a portion of the aponeurosis of the occipito-frontalis muscle sloughs away; and this may take place without any ultimate injury: but we never find the scalp take on such action, which fact is accounted for by the great vascularity of its texture.

Nævus of the Scalp Treated by Tartar Emetic.

ANNE SHALLARD, aged nine months, was admitted into the Queen's Hospital, under the care of Mr. Sands Cox, February, 1851, on account of a nævus situated over the right parietal bone, about the size of a half-crown piece. The mother stated that a slight discolouration of the scalp was observed at birth; that it remained stationary for some time, but eventually

began to increase, and had during the last two months attained its present size. There was no pulsation evident in the tumour, which was of a bluish cast, and slightly raised above the adjoining integument. The child's general health was good, and all the functions regular; but a branch of the temporal artery was enlarged, and could be traced almost into the diseased parts. On the third day after admission Mr. Sands Cox ordered the potassio-tartrate of antimony to be applied, which was accordingly done. In two days, the application having been several times repeated, the whole of the discoloured portion was converted into a pustular mass, and this with but little or no inflammation or irritation of the scalp. Poultices were now applied, and in the course of a week there was a healthy granulating surface, which was cicatrized entirely three weeks afterwards. The patient left the hospital without any appearance of returning disease, and some time after continued quite well.

Dupuytren considered tumours of this description to be a kind of erectile tissue, to which they certainly have a considerable resemblance. There are several varieties, which have been classed differently by various authors; perhaps the best mode of describing them is to divide them into the cutaneous and subcutaneous, although it must be confessed that we frequently meet with specimens which partake of both these varieties. Some have divided them into venous, arterial, and mixed, according as they were thought to contain more of arterial or venous tissue in their structure. This, however, can only be judged of by the colour, which must be a deceptive mode of forming an opinion, as at certain times the colour is much deepened. Nævi are popularly supposed to arise from some influence of the mother's mind on the foetus, and are frequently supposed to bear a resemblance to something definite; but as they are oftentimes of various and fantastic forms, it is easy to invent a likeness to some known object. Still, however, the influence of the mother's mind may have something to do with it, as it is a well ascertained fact that the foetus may be disfigured, should the mother undergo any strong mental exertion.* Nævi frequently remain stationary during life, hardly requiring any interference; but if they present a disposition to grow, and appear inclined to attain any considerable size, it is prudent to recommend their extirpation by one of the many methods adequate to that purpose. For the cutaneous variety, pressure will sometimes succeed; and the continued application of collodion has, with small nævi, been followed by success. Nitrate of silver and caustic potash have also been used, likewise vaccination; all evidently acting in the same way as the tartar emetic,—producing inflammation and suppuration, and thereby destroying the diseased texture. If, however, the nævus is of the subcutaneous kind, other methods must be had recourse to, and the ligature or

* In proof of this, some time ago the writer saw a child minus the left hand, which appeared to have been amputated, there being a cicatrix, &c., as after the operation. The mother stated she had during pregnancy been much frightened by seeing a beggar on whom amputation of the forearm had been performed.

knife then present themselves for use; but, from the immense hæmorrhage which takes place if these tumours are cut into, the former is the most in vogue. If the knife is used, the rule laid down by Cooper should be adhered to—"not to cut into the tumour, but to cut it out;" and the whole must be taken away, else what is left will certainly continue to grow as before. Mr. Keate first applied the ligature for the cure of this disease; and he has been followed by many other eminent surgeons, as the cases related in "*The Mirror*" show, with great success. *Lancet*, 1850, Vol. I., p. 127, 129, 246, 421; Vol. II., p. 31. 1852, Vol. I., p. 74.

Stricture of the Urethra.

GEORGE HUMPAGE, aged 40, affected with stricture of the urethra, admitted into the Queen's Hospital October 25th, under the care of Mr. Parker. On examination, his bladder was found greatly distended; he complained of much pain, and a constant desire to pass water, which he could only do by drops. The urine was clear and did not deposit. He could not sleep at night, and his countenance was haggard, and showed signs of acute and long-continued suffering. His bowels were moved daily, but his appetite was gone. It appeared that he had experienced much difficulty in passing his water during the last two years; that he had neglected it, and in consequence had become gradually unable to make the slightest stream. He had frequently suffered from gonorrhœa. On a bougie being introduced, the whole of the urethra was found to be in a hardened, semi-cartilaginous state, and the smallest instrument could not be passed more than three inches and a half. As the patient complained very bitterly, it became a question what treatment should be adopted; but a sufficient quantity of urine passing during the twenty-four hours, Mr. Parker ordered a bougie to be introduced daily, and suffered to remain a short time, while the patient took five grains of soap and opium pill at bed-time.

This treatment was continued until Nov. 15th, an occasional dose of castor oil being required to regulate the bowels. The bougie would pass about four inches, but was then stopped by an impediment harder than anything which had been overcome. A small silver catheter was now used; and in two or three days it could be readily passed as far as the membranous portion. He was now put in a warm bath daily, and on two or three occasions had leeches applied to the perineum, the catheter being used after each bath. On November 26th, No. 6 catheter was passed fairly into the bladder, and a considerable quantity of urine taken away. The instrument was allowed to remain for an hour. On November 30th it was again introduced, secured by tapes, and kept in the bladder about thirty-six hours, during which time suppuration was established; and on its removal the patient, in a few days, could make water with great facility, and in almost as good a stream as he ever could. On his discharge he was free of pain, much increased in weight, and his countenance showed none of the haggard appearance it

did on admission. No. 8 catheter could also be passed with perfect ease. He was advised to have a bougie passed at intervals for some time.

Concerning the treatment of strictured urethra there has always been a great variety of opinion; and at the present time the differences do not seem much diminished, each party advocating their own peculiar treatment. It seems, however, proper that this should be swayed by concomitant circumstances, and that the state of the urethra as regards its denseness, its irregularity, its cartilaginous condition, and the fact of there being a false passage (if such be the case) should be taken into consideration. But it is tolerably certain, that so long as a patient makes a sufficient quantity of water, although guttatum, the knife should not be resorted to, as no incision can be made without some risk of unpleasant consequences; and this is the more evident, when other and milder procedure not calculated to bring life into danger, will effect the desired object. Cooper says:—"The cure by dilatation may be regarded as that which, on the whole, retains the greatest share of approbation, and in the case reported (as bad a one as could well occur) the use of the catheter and bougie succeeded admirably. Had sudden retention occurred, or had not a sufficient quantity of urine passed, the knife would have been requisite. Liston remarks, in speaking of the treatment of stricture by the catheter:—"There are few strictures indeed which will not yield to this treatment;" and afterwards, "incision of stricture may be required in retention, scarcely otherwise."

Provincial Medical & Surgical Journal.

WEDNESDAY, MARCH 3, 1852.

A TRIAL has recently taken place at the Marylebone County Court, which presents matter of considerable importance to provincial practitioners, especially those who are engaged in consultation practice.

It appears that Mr. BROWN, a consulting-surgeon residing in London, was summoned a distance of 150 miles to visit a patient, for which his charge was £39.7s.6d. This demand was resisted by the patient's friends, as exorbitant! For the plaintiff, several witnesses were called, who spoke of the customary fees of London physicians and surgeons for country visits, as varying from 10s. 6d. and upwards per mile; stating also that the amount charged in the case in question was below the average fee.

The reflections suggested by this transaction point to the necessity which exists for something like regularity in the demands of metropolitan consulting practitioners. Now that

labour and time expended in travelling are both so much curtailed by railways, it would not, of course, be reasonable to adhere to the old posting fee of £1. 1s. per mile; but it is equally unreasonable, as well as undignified, that a London consulting-practitioner should travel, in proportion to distance, for less than a provincial physician or surgeon of repute would think himself entitled to demand. To do so is to take a most unfair advantage of the, in many cases, foolish prejudice in favour of metropolitan advice. As regards the sum charged by Mr. BROWN, it is small in comparison with the charges of those physicians and surgeons who are most frequently summoned from London; and it betrays a most despicable meanness on the part of the defendant to dispute a demand so liberal. It is plain that Mr. BROWN had exercised a charitable consideration for his patient.

It is obviously of great importance to the mutual good understanding of provincial and metropolitan practitioners that nothing like "underselling" should be countenanced, but that, except under special circumstances, some uniform rate of charge should be made; and we are inclined to agree with one of our London contemporaries that half a guinea per mile "out" by railway would be both equitable towards the patient and honourable towards the country physician and consulting-surgeon. We allude, of course, here, to those whom a well-earned reputation has placed high in the confidence of the profession. There are, we are aware, not a few in the great Babylon who endeavour, by sundry more clever than creditable manœuvres, to secure a consultation practice, which would never reach them in a more legitimate way. It were vain to expect such to adhere to any recognized rule of conduct whether pecuniary or otherwise. Among these latter it need hardly be said, we do not class Mr. BROWN.

Reviews.

Medical Aspects of Death, and the Medical Aspects of the Human Mind. By JAMES BOWER HARRISON, M.R.C.S.L., &c., formerly one of the Resident Medical Officers of the Manchester Royal Infirmary, &c., &c.

In this little volume Mr. Harrison presents us with a couple of remarkably readable and pleasantly-written essays on two subjects, neither

of which it is easy to treat pleasantly. In his preface, the author *naïvely* observes that he has "never thought it essential that a book should be dry in order to be useful." We think that he has produced a useful book; we are sure that he has not added to the stock of dry ones.

In the first essay, the premonitory signs of death, the several modes in which death is occasioned, and the indications of death having really taken place, are discussed with an absence of disagreeable detail, and yet with a fulness of description that bespeak a skilful and not unpractised hand. We do not know of any other work in which the unprofessional reader could meet with the same information so intelligibly and pleasingly conveyed, nor in which the medical man would find the subject so appositely garnished with anecdotes and classical quotations. The following is interesting:—

"In order to provide against premature interment, the Romans are said to have waited seven days before they interred the dead; those who had charge of the corpse calling the name of the deceased many times in a loud voice. It was this custom which constituted the Conclamatio. Just before the body was finally buried, the name was again loudly called; and then it was considered proper to enter on the funeral ceremonies. Terence makes allusion to this custom, when he says:—

‘Desire,—jam conclamatum est.’”

Those who dread the possibility of premature interment will be glad to read our next quotation:

"It would seem, then, that the indications of death are sufficiently marked to render it improbable that premature interment can often take place; and whenever this occurs, it must be the result of great carelessness, ignorance, and haste."

We recollect a case of cholera in which considerable excitement was occasioned in the mind of the public by the circumstance of the corpse becoming warm some hours after death. The not infrequent occurrence of this phenomenon after death from cholera does not escape notice in the work before us.

We extract the following for its practical bearing. It indicates the professional acumen of the coroner for Middlesex, and sufficiently proves the desirableness of selecting members of the medical profession to fill the important office of coroner.

"A man, who had just been married, got into a dispute with one of his own party, and was knocked down by a blow. Eventually he was able to rejoin his party; but it was observed that whilst engaged at his dinner he hastily got up and went out of the room. A friend followed him, but immediately returned to announce that

the man was dead. On examining the body after death, a surgeon pronounced that he had died from apoplexy, and attributed the fit to the injuries he had received in the quarrel. The coroner (Mr. Wakley) asked the surgeon if he had examined the windpipe. The surgeon confessed that he had not done so; whereupon he was desired to complete the examination. He repaired presently to perform his task, and on his return stated that he found a piece of meat wedged firmly in the glottis. Thus death had in reality arisen from this source; and the congested state of the brain was the effect of impeded respiration, and not the first occasion of his death."

As a specimen of the curious information the reader will find in the work, we select an instance of a judicial sentence unworthy of Pagan barbarism. It occurred in England in the reign of George the Second.

"Strangeways refusing to plead at the bar, was sentenced by Lord Chief Justice Glynn, "to be put into a mean house, stopped from any light, and that he be laid upon his back, with his body bare, and his arms and legs stretched by cords in opposite directions; and that upon his body shall be laid as much iron and stone as he can bear, and *more*; and the first day he shall have three morsels of barley-bread; and the next shall he drink thrice of the water in the next channel to the prison door, but of no spring or fountain: and this shall be his punishment till he die.' On the Monday following, at eleven in the forenoon, the sheriffs and their officers came to the press yard, whither the miserable prisoner was presently brought. He wore a mourning cloak, beneath which he appeared clothed in white from head to foot. By the sheriffs he was conducted to a dungeon, where, after prayers, his friends placed themselves at the corner of the press, whom he desired, when he gave the word, to lay on the weights! This they did at the signal—"Lord Jesus receive my soul;" but finding the weight too light for sudden execution, many of those standing by added their burdens to disburthen him of his pain. He died in about eight or ten minutes."

The second essay touches pointedly but gently upon the slighter deviations from health of mind; such as not constituting acknowledged insanity are still indicative of disorder of the mental balance. To do justice to Mr. Harrison's mode of treating his subject, we should have to transcribe his essay. We take at random an extract or two as illustrations of the author's style.

"There is a story told of a cockney, who visited the beautiful and romantic scenery of the Alps, and being asked his impression of a sublime prospect which suddenly burst on his view, said, that he must confess 'it was a well got up thing.' This is the school of fashion which gives us two fingers to touch as a welcome, after the absence of as many years."

"Man is perhaps as beautiful in the passions and affections of his nature as in the highest reach of his intellectual powers. Terrible indeed are the passions,

but they are also glorious and lovely. The very emotions, feelings, and instructive impulses of our nature constitute more than all else our humanity. The cold calculations of the strongest minds are dead without the warm influence of affection: and we would rather pardon the forwardness of childhood, and the caprice of women, than lose all those endearing sentiments which bind us to the one and to the other."

We need scarcely say that we commend this work to our readers. It is such as we may frequently find convenient to place in the hands of our more intelligent patients. The author has managed to combine the *utile* with the *dulce* in a way which must ensure success.

Proceedings of Societies.

[SINCE our last publication the opinions of the members constituting the NORTH WALES, WEST SOMERSET, BATH AND BRISTOL, and YORKSHIRE BRANCHES, have been obtained on the several clauses in the New Medical Reform Bill, either by a meeting of the branch or by writing individually to each member. The conclusions arrived at will be found embodied in the subjoined letters, which have been obligingly forwarded by the Secretaries for publication.]

NORTH-WALES BRANCH.

To J. P. Sheppard, Esq., Secretary to the Council.

SIR,—Having perused the "Draft of the Proposed Medical Bill," as published in the *Journal* of Jan. 21st, 1852, I give my approval of the Bill as a whole, but would hope to see some little alteration when it comes to be considered in detail. I hail with especial satisfaction the uniformity of education and qualification, and that the profession is to be entered by *one* common portal, leaving gentlemen at liberty to choose and advance with that branch, (be it surgery or medicine,) most congenial to their taste and interest. I, however, dislike the proposed name, that of "Licentiate in Medicine, Surgery, and Midwifery," and would suggest that the present name of Surgeon be given to this class; and that the higher grade of Member of the Royal College of Physicians and Surgeons be respectively designated *M.D.*, Doctor of Medicine, or *Ch. D.*, or *C.D.*, Doctor of Surgery, and that they may be commonly styled Dr. A., or Doctor B. In Clause 13 I would suggest that the year begin January 1st instead of February 1st.

Clause 15.—I advocate the system of a short apprenticeship or *pupilage*, called "articled pupil," when habits of business may be formed, and the mode of conducting a practice may be acquired, as well as familiarity with drugs, minor operations, &c., &c., two or three years being sufficiently long.

Clause 17.—I like the formation of a Provident Fund,

but dislike the *annual* trouble and annoyance of registering. Could it not be made *optional* for a person to pay one larger sum instead?

Clause 36.—I should wish to see the clause having reference to the business of druggists and chemists made *more stringent*, and such as would compel them to abstain from prescribing and dispensing their own nostrums—a practice *very prevalent* and injurious in country districts.

Clause 13.—I hope we, who reside in the provinces, will not be obliged to “produce our diplomas” at the Registrar’s office, in order to secure our registration, as that would involve a risk of losing an important document in its transit through the post-office, or otherwise, as well as a considerable expense to the parties. I hope that the “attested certificate,” together with a reference to the books of the several Colleges and Halls, may suffice.

I trust that nothing in this Bill will have a retrospective and injurious influence upon those *British* Colleges and Universities at present possessing certain privileges.

E. WILLIAMS,

District Secretary to the North-Wales Branch.

Wrexham, February 16, 1852.

Llangefni, Feb. 12, 1852.

MY DEAR SIR,—I have only to-day received the whole of the replies to my circular letter respecting the “Draft of the Proposed Bill for Medical Reform,” and hasten to communicate the result to you, by giving a short account of the doings of the North Wales Branch upon that interesting subject.

With *one solitary exception*, in the person of Mr. Walthew, of Holyhead, (an old and experienced and very respectable practitioner,) all the others *agree* and *heartily approve* of the *principles* of the proposed bill generally. Many of them have offered suggestions, and some only of which I think it my duty to particularize.

Dr. John Roberts, of Bangor, warmly approves of “the plan to set aside a portion of the registration-fee to form a benevolent fund, for (he continues to write) I feel convinced that no *practical* good can result from a fund supported entirely by voluntary contributions.” In this sentiment he meets with a *heartily seconder* in me.

Mr. Owen Richards, of Bala, who approves of the leading principles of the bill, inquires :—“By clause 3, the Society of Apothecaries is empowered to choose six Members of Council; in the event of the existing powers of the Society being resigned or abolished, by whom should the six members be chosen?” Again, he says of clause 26 :—“The object of this clause will be virtually defeated unless it be clearly defined what constitutes an act of practising in any of the capacities specified, and unless the evidence required to convict be made as simple as possible. The great difficulty of obtaining a conviction under the Apothecaries’ Act turned upon these two points.”

Mr. Thos. Charles, of Bangor, says :—“I should have been glad had it been practicable, to give the profession more elective power in the appointment of the Medical Council.” But upon the whole he considers the proposed bill a very good one and will support it.

Mr. Robert Jones, of Carnarvon, “approves most highly of the proposed bill for the regulation of the profession,” and communicates very gratifying news for the welfare and success of the North-Wales Branch, at least as I consider it, by stating, —“I am glad to inform you that Mr. Hamilton Roberts has this day authorized me to add his name to the list of our members, and beg you will enrol him.”

Mr. Lloyd, of this place, is conspicuous amongst the approvers of the intended measure. Besides those I have here mentioned, there are some five or six members who think with Mr. George Frederick Wills, of Crewkerne, (*vide Medical and Surgical Journal* of the 4th ult.,) that some *very stringent* clause should be embodied in the proposed bill, to prevent chemists and druggists from *practising as surgeons and apothecaries*. To this expression of feeling upon their part I must add my own and Mr. Lloyd’s concurrence. I know too well that the druggists in this and the adjacent counties do nearly, if not more than, as much as the regular medical practitioner in *prescribing and dispensing* medicines. Why should this be allowed? Upon what grounds of justice and equity should it be permitted, I ask? I have heard medical friends say that they are aware the druggists frequently *visit* before giving medicines, and I can testify (as also can Mr. Lloyd) that the statement is perfectly correct as far as it concerns this county. I do hope our wise legislators will not lose sight of this most outrageous and anomalous state of things.

As I said before, there was only Mr. Walthew who disagreed with the proposed Medical Reform Bill. I will just recite his own words :—“In answer, I beg to say there are many parts in it which meet with my approbation, but I cannot affix my name to any measure of reform which does not recognize the privileges of the Apothecaries’ Company, as granted to them by the Act of 1815. I am also one of those who think that every student should serve an apprenticeship. As the proposed bill does not appear to me to be clear on these points I must decline supporting it.”

I have now concluded all I have to say, and you can make whatever use you think proper of it.

I remain, yours very truly,

D. KENT JONES.

District Secretary North Wales Branch.

Dr. Williams, Wrexham.

P. Lardner Green, Esq., of Buckley, Flintshire, and T. T. Griffiths, Esq., of Wrexham, write to the following effect :—

Buckley, Flintshire,
February 13th. 1852.

DEAR SIR,—In accordance with the wish expressed in the circular you sent me, I beg to offer the following observations upon the “Draft of the Bill for Reforming the Profession.” There can be no doubt of the imperative necessity of having in force a Bill to legislate for the profession *as a whole*; the proposed Bill appears, with some exceptions, to be the best yet proposed, and perhaps equal to any we can expect in the existing state of public opinion :—

1. The payment of the fee of £10 seems unnecessarily low. Those who will pass the Examining Board will possess a legal title to practise *all the branches of the profession*, equal to those who now hold the double qualification, and who have paid a higher sum; nor ought the diminished and diminishing value of money be lost sight of in making this regulation.

2. I see no good reason why the annual certificates should commence on February 1st, but, on the contrary, think there would be some advantages in their being dated January 1st.

3. That practitioners who had held certificates during five years be entitled to claim to the Benevolent Fund, though to a less amount than those who have held for ten years.

4. A well-marked distinction should be drawn between the degree of culpability attributed to, and the consequent amount of penalties incurred by, two distinct classes of irregular practitioners,—viz., *on the one hand*, those who would be regularly qualified members of the profession, and had been registered previously as such, but who may not possess the current annual certificate; *and, on the other*, those who not only would be without the annual certificate, but who had never been registered, nor had ever entered into the profession, and who would be, in fact, mere quacks.

5. That the Examining Board require students, attending lectures and hospital practice, to register their names personally *three times* at least during each session, and during the same time to enter their names twice a week in a book kept at the respective hospitals. That a visitor (or visitors) be appointed by the Examiners, who shall inspect the various classes of students during lecture hours, each class being visited twice at least during each session.

6. That the Board of Examiners be required to examine each candidate upon anatomy with the *recent subject*, and that *one examination, or a part of an examination, shall be with papers, to which the candidate shall give written answers*. To these last regulations I attach much importance.

7. To add a clause to the Bill to empower the Medical Council of England to take charge of the proposed Medical Benevolent College, (should it be completed,) and to govern the same upon certain conditions.

In conclusion, I hope the Bill will be introduced into Parliament without loss of time, and after due consideration become law, and thus see the long-wished for result of the union of the *disjuncta membra* of our profession, the welfare of which is so important to the public as well as to ourselves.

I am, dear Sir,

Yours very truly,

Dr. Williams.

P. LARDNER GREEN.

Chester Street, Wrexham.

SIR,—After a careful perusal of the "Draft of the Proposed Bill," I cannot but consider its adoption as most desirable in almost all its provisions. The point that appears to me most to require reconsideration, is

the age (21) at which a young man becomes entitled to enter upon all the responsibilities of independent practice. And it may happen, and often does, that within a year or two of commencing practice, cases in midwifery, surgery, or medicine, of the most urgent nature and important character, may depend upon the decisions of his judgment. I wish the age were 22, because that additional year matures a young man's judgment, adds to his knowledge and experience, and acquaints him more fully with the realities of life, and of those important professional duties and responsibilities he is about to take upon himself. I think four years too short a period for a young man to acquire that knowledge of, and familiarity with, diseases that even in commencing practice he is supposed to possess. I should prefer five years, because two years might be passed in the surgery of an experienced practitioner, with many advantageous results. The shortness of the time would lead a young man to commence at once; and from the beginning, the study of at least the elements of his profession, he would acquaint himself with the appearance, properties, doses, and uses of drugs and medicinal preparations in a practical manner, to be, I believe, acquired in no other way. He learns the habits of private practice—a lesson never to be acquired in hospitals; he benefits by the practice and experience of his principal; he acquires habits of business and punctuality; and, in the quietness of private practice, he has an opportunity of feeling those requirements, the value and the possession of which he sees are essential to successful practice, and thus he will probably be led to arrange for himself those objects of study when he attends lectures and hospitals, which his own particular genius or taste, or which the peculiar requirements of private practice, or the importance of particular cases as then observed, may render most interesting, valuable, and important in his estimation. And these views may be confirmed by following a young man into general practice at 21, who has passed from school to the study of the higher branches of the profession in ignorance of its elements. He studies his profession rather as an abstract science, for he has had little or no opportunity of estimating its close and important connection with the moral as well as physical wants, distresses, welfare, and happiness of those who are to depend upon him for counsel, direction, and support, under urgent and severe trials of bodily and mental distress and suffering. A wide field is suddenly opened to his untutored mind and judgment; he feels that it contains the treasure important to his future well-doing, but in the multiplicity of objects he is at a loss how to select those most immediately necessary to that knowledge, without which he could not conscientiously even *commence* practice, and as this bill will mainly affect the great body of general practitioners, these observations are intended to apply chiefly to them.

Dr. Williams.

T. T. GRIFFITH.

WEST SOMERSET BRANCH.

To J. P. Sheppard, Esq., Secretary to the Council.

SIR,—On receiving your letter, dated Jan. 22nd, containing the request of the Central Council that I should submit the "Draft of the Bill for Medical Reform" to a meeting of the members of this Branch, I convened the Local Council for the 24th of January, when it was resolved to hold a special meeting of the Branch to consider the said Draft Bill, on the 4th of February. I have been unable to communicate to the Central Council earlier the results of that meeting.

The Draft Bill was considered by the meeting with great attention, section by section; and I was instructed to communicate to the Central Council the earnest desire felt by the Branch for a permanent and satisfactory settlement of the Medical Reform question, and its unanimous and full approbation of the general principles of the proposed Bill.

At the same time I was instructed to submit the following remarks and questions on the details of the said bill to the consideration of the Central Council, which were unanimously agreed to by the meeting:—

With reference to Section 11, I am to ask whether it is intended that the Examining Boards for the three kingdoms are to be chosen from the Council, or from the profession at large?

In Section 13 what provision is to be made for the registration of qualified members of the profession who may be absent from the country, or otherwise prevented registering within the time prescribed by the bill? Also, should it not be compulsory to prove *legal possession* of the diploma, certificate, or licence, if required? Or, should there not be some provision to prevent persons holding diplomas, &c., illegally, from registering?

In Section 16 cannot a clause be inserted making it the duty of the Medical Councils in congress to cause a uniform Pharmacopœia, to be drawn up and published in place of the widely-differing Pharmacopœias now issued by the three Colleges of Physicians?

In Section 19 should it not be the duty of the Medical Councils to cause an annual statement of the income and expenditure to be published?

In Section 21 are we right in assuming that, by Section 17, persons who may have transferred, will be able to renew their certificate without further reference to their original country?

In Section 22 what provision is to be made for the great majority of provincial physicians who now hold hospital appointments, and practise, without being members of any College of Physicians? Are they to be compelled to join one of the Colleges, whether they will or not?

In sections 26 and 30 the members of this Branch are unanimously and strongly of opinion, that the profession would, as a general rule, be safer under the decision of the Judges of the County Courts than under a single, irresponsible, and often strongly prejudiced magistrate; and, if it be practicable, would press this

proposed alteration on the Council and framers of the bill.

In Section 27 I am to suggest, that the number of registered practitioners to complain to the Medical Council, &c., should be not less than five, it being felt, that when sufficient ground of complaint existed, there would be no difficulty in procuring the assent of that number to the complaint, while at the same time it is highly necessary to guard and protect individual members of the profession from frivolous or vexatious complaint.

I am, dear Sir,

Very faithfully yours,

F. H. WOODFORDE, M.D., Hon. Sec.

Taunton, February 18, 1852.

BATH AND BRISTOL BRANCH.

To J. P. Sheppard, Esq., Secretary to the Council.

SIR,—In compliance with the request contained in your notes of January 22nd, Mr. Bartrum and myself have written to every individual member of the Bath and Bristol Branch of the Association, for an expression of their opinion on the "Draft of the Proposed Medical Reform Bill." We have also had meetings of the Council to take the replies into consideration, and after carefully doing so, in conjunction with the bill itself, have agreed to the following report as from the Bath and Bristol Branch, viz.:—That

In Clause 11 the word *yearly* be struck out.

Clause 14.—They *strongly approve of*; as it proposes that all candidates for a licence to practise should pass the same preliminary examination.

Clauses 18 and 19.—They are quite of opinion that the *whole surplus receipts* after payment of the working expenses of the Act should be devoted to the one object—a *provident fund*; the regulation of which must vest in the Council.

Clause 22.—Does this clause exclude British graduates from registering as physicians unless they become members of the College of Physicians of the country in which they practise, such physicians having been in practice prior to the passing of this Bill? Will not this make the degrees of British Universities a dead letter?

Clause 26.—The punishment is too summary. The party offending should be proceeded against in the County Court. The party prosecuting should be deputed by the Council of the country in which the offender resides. The general tenor of the law of prosecution should be similar to that *at present* in use under the Apothecaries' Act.

Clause 27.—The Governing Body or Council should have the power of expelling disgraceful members, but should not be required to call on any individual for his defence, unless the *ex parte* or *prima facie* evidence were such as to be satisfactory to themselves, and not merely because A. B. and C. form a cabal, and think fit to denounce any one who may be, perhaps, quite innocent of the charge.

Clauses 29 and 30.—For *one* read *two* justices, one being too irresponsible.

Clause 33.—Highly approved.

Clause 34.—Is it intended to ignore all degrees in medicine, *provided the Council have a proper control over the various University Examiners?* The possessor of the degree of M.D. at any recognised university should, on payment of a small fee, *be at once admitted a member of the College of Physicians of the country in which he may practise, and be entitled to transfer his name from the College of one country to that of any other in which he may desire to practise.*

Clause 39 requires modification, unless the Council have the power to *reinstate* a member thus excluded,—Suppose a man be found guilty of manslaughter, should that entirely exclude him?

With the above exceptions and modifications the Councils cordially approve of the aforesaid “Bill to Produce Uniformity of Medical Education,” &c.

I remain, my dear Sir,

Yours faithfully,

J. COLTHURST, Hon. Sec.

11, The Mall, Clifton,

February 22, 1852.

LIVERPOOL

MEDICO-ETHICAL SOCIETY.

To J. P. Sheppard, Esq., Secretary to the Council of the Provincial Medical and Surgical Association.

SIR,—I am directed by the Council of the Liverpool Medico-Ethical Society to inform you, that at a meeting held on the 17th ult., the following resolution was agreed to:—

“That this Council desire to express their approbation of the general tenor of the ‘Medical Bill’ proposed by the Provincial Medical and Surgical Association.”

At the same meeting a Committee was appointed, which reported upon the Bill yesterday, and offered some suggestions for the consideration of the framers, these I am also directed to send you, they form the concluding portion of the following paper:—

The Committee appointed to consider the “Proposed Medical Bill,” beg to report, for the information of the Council, that they consider that the following are the most important principles contained therein:—

The repeal of previous statutes, including part of the Apothecaries’ Act, thus producing uniformity and simplicity in the law.

The appointment of a Medical Council, with power to direct uniformity of education and competent examination.

The formation of a body of Licentiates in Medicine, Surgery, and Midwifery, independent of any existing bodies, which alone will have a licence to practise.

Reciprocity of practice throughout the United Kingdom.

Registration of legally-qualified practitioners.

Annual payments for licence to practise.

The compulsory formation of a benevolent fund.

The protecting the registered practitioner by certain legal powers and privileges.

The punishment of unregistered or irregular practitioners, or those who misconduct themselves.

They recommend that a separate vote of the Council should be taken upon each of these principles, and the following points for the consideration of the framers of the Bill:—

Whether the Council be elected on the representative principle? Whether, if so, it be distinctly stated how—i.e., whether by the bodies, or their executive? Whether, when the licensing power be taken away from the Apothecaries’ Company, it will not be advisable to have six persons, chosen by the Licentiates themselves, in place of those elected by the Society of Apothecaries?

Whether the Clauses against quacks and irregular practitioners are not too stringent?

Whether midwives shall be exempted from the Act by name?

Whether a shorter name may not be devised for Licentiates than that proposed in the bill?

I remain, Sir, yours &c.,

JOHN HARRICKS,

Secretary to the Medico-Ethical Society.

Liverpool, February 24, 1852.

In that portion of our impression devoted to general correspondence, (p. 127,) will be found two other letters upon this subject, to which we beg to refer the Members of the Association, as also our readers generally. We have also received the report of the meeting at Leeds, which is printed at page 130, having arrived too late for insertion in its proper place.

Foreign Department.

FRANCE.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

Distribution of Prizes.

THE prize of the Academie de Medicine for 1851, value 1,500 francs (£60), was awarded to DR. RICHER, for the best essay “On White Swellings,”

The Portal Prize, 1,200 francs, for the best essay “On the Normal Anatomy of the Liver, and the Nature of the Pathological condition called *Fatty Liver*,” was not decreed.

The prizes for the year 1853 are as follows:—

The Academy Prize of 1,000 fr. (£40) will be given to the author of the best essay on the question—“Does Paraplegia occur independently of Myelitis? If so, to trace its history.”

The “Portal” Prize of 1,000 francs is for the best essay “On the Nature and Treatment of Goitre.”

A prize of 1,500 francs for a “History of Tetanus.”

A prize founded by Dr. Capuron, 1,000 francs, for

the best essay "On the Physiology and Pathology of the Puerperal State."

The "Itard" Prize of 3,000 francs (£120) for the best memoir on some subject connected with practical medicine. This will be awarded in the present year.

The "Argenteuil" Prize for the author of the most important improvement in the treatment of strictures of the urethra, not having been awarded for some time, in consequence of want of merit in the candidates, now amounts to 12,000 francs (£480).

The "Civrieux" Prize of 1,200 francs has for its subject the "Pathology of Epilepsy."

Treatment of Ununited Fracture of the Patella.

Fractures of the patella sometimes fail in becoming consolidated, but are united by ligamentous tissue, which is incompetent to sustain the necessary movements of the knee-joint. A case of this kind is recorded by M. Bonnet (*Revue Medico-Chirurgicale*), in which he obtained bony union by a peculiar process, which, together with section of the triceps muscle, is thus narrated:—

The subject of this case was a vigorous man, aged 44, who had been treated for fracture of the patella in the usual manner, without inducing consolidation. He therefore entered the Hotel Dieu of Lyons, under the care of M. Bonnet, who considered that some amelioration, at least, might be accomplished by section of the triceps, and after scarifying the ends of the bones, keeping them in contact by clamps, as suggested by M. Malgaigne.

Accordingly, M. Bonnet commenced by subcutaneous section of the triceps, a few lines above the upper fragment. This allowed the descent of the fragment, which, together with the lower portion of the bone, was scarified by two other subcutaneous punctures; and the limb was then placed in appropriate splints, with the heel elevated. For the first few days there was some swelling of the joint; but the inflammation speedily subsided, and M. Bonnet proceeded to complete the operation by inserting small screws into each fragment, and causing these to be brought together, and retained in apposition by waxed thread. The screws are said to have remained forty days without producing any other unpleasant effects than some hydrarthrosis. The result was highly satisfactory, the fragments being brought nearly into apposition, and the uniting tissue being sufficiently resisting to allow of active use of the limb.

On the Treatment of Erythematous Lupus.

By M. ARAN.

M. Aran (*Union Médicale*, Janv. 19, 1851,) gives this name to a form of lupus which destroys the surface only of the integument. Bielt called it "Centrifugal Lupus," because it spreads in a circular manner, invading, in some cases, the entire face, and leaving the integuments depressed as it creeps onwards. The disease is almost confined to the face, where it commences in the form of red patches of the size of a

shilling, or larger, and leaving a cicatrix resembling that of a burn. Another form more common than the above attacks the end of the nose, producing a redness similar to that of a chilblain. After a time the skin becomes thinner, and ulceration occurs. This form is most common in females. The treatment recommended by M. Aran consists in steam douches to the part, with laxatives and sudorifics.

[It has occurred to us to treat several of these cases successfully. The means adopted were the steam douche twice a-day for a period of twenty minutes, and cod-liver oil internally. We have never found any material benefit from lotions or ointments, so commonly prescribed in these cases.—ED. P. J.]

Brachial Neuralgia.

M. Neucourt (*Archives Générales and Medical Times*) speaks of a form of neuralgia, which he thinks has excited but little attention. Pain is, of course, a chief symptom, but it exists in very various degrees, from that which scarcely calls for attention to the most exquisite. In some cases, too, whatever is done, it obstinately continues; but in most, in proportion to the duration of the disease, its severity abates. Although with this spontaneous pain there is usually associated pain on pressure, the latter is sometimes quite absent, while in other cases it may be so marked as to become a true dermalgia. Pain on moving the arm is a very constant symptom, even when the other two forms are absent, the least movement sometimes causing such suffering as to compel the patient to keep himself quite motionless. Sometimes it is only certain movements that are painful; and when there is great pain on movement there may be none from pressure. Muscular paralysis is another occasional consequence of neuralgia, especially when the pains have been intense. The deltoid is oftenest affected. Each portion of the brachial plexus may be the seat of the neuralgia, which may thus be termed cervical, scapulo-thoracic, or humero-palmar, according to which portion is chiefly implicated. All may be so, but usually a portion only is; the cervical is the least, and the thoracic the most frequent. It is rare to find the pains following the direction and distribution of the nervous branches, they being usually confined to some limited region, as the point of the shoulder, lateral part of the chest, elbow, &c. There is rarely any fever present, the pulse being usually quiet. Insomnia is a marked symptom, even in the absence of severe pain. With respect to the prognosis of the disease, it may be observed, that in its acute form it is often of no great severity, and soon disappears, even without aid; but in other of such cases, the pains are excessive, and resist the operations of remedies with obstinacy, which, however, when they do not relieve the pain, often may prevent the affection falling into a chronic condition. The worst cases are those which are originally chronic, coming on imperceptibly at first, and gradually increasing in severity and obstinacy. In several cases the disease attacks persons apparently quite well, and

without any obvious cause. Still, external agents exert a great influence in determining diseases that are especially attended with pain, and this one offers no exception; great extremes of cold and heat being common exciting causes of it.

Treatment.—Some of the cases pursue their course in spite of all treatment, and yet get well whatever means be used, so that it is often difficult to assign the share due to nature and that due to the remedy. In others, however, long left to nature without improvement, the efficient aid of medicine is undeniable. Leeching is very useful in the strong and plethoric, and emollient cataplasms are valuable adjuvants, or in other cases substitutes. A plaster of treacle, powdered with opium and surrounded by diachylon, forms a good application, as does a liniment formed of one ounce of almond oil and six to eight grains of hydrochlorate of morphia. As antiphlogistics act best in the strong and plethoric, so are narcotics best adapted for delicate and nervous subjects, failing in the former unless preceded by bleeding. After these two classes of means, revulsives often exert a decidedly good effect, and in particular cases various remedies, as shampooing, acupuncture, electropuncture, and the iodide of potassium, are useful. Sudorifics are not useful remedies, though sweating from a vapour-bath has proved very efficacious.

On Catarrhal and Lobular Pneumonia of Infancy.

The *Union Médicale*, Sep. 1851, contained an article on this subject by M. Trousseau, who considers that, although the different inflammations known as lobular pneumonia, capillary bronchitis, catarrhal pneumonia, &c., have been accurately described, practitioners in general have but a very indistinct conception of their differences. Simple pneumonia and catarrhal pneumonia are, M. Trousseau maintains, as distinct as are small pox and erythema, and this he proceeds to show by the difference in the mortality of each.

In the six months of his clinical practice in the "Hôpital des Enfants Malades," of twenty children attacked by simple pneumonia, not one died; while on the other hand, of thirty infants the subject of catarrhal pneumonia, not one survived. He further lays down the differential diagnosis of these diseases as follows:—

Simple Acute Pneumonia seldom or never attacks a child under the age of two years; it is not often seen under three years, but it becomes more common as age advances. The symptoms are much the same as in the adult, but the crepitous râle is never heard, the respiration becoming at once bronchial. The progress of the disease is more rapid than in the adult, but the mortality, as before said, is very small. The treatment adopted by M. Trousseau consists in bleeding according to the age and strength of the child, followed by tartar emetic.

Catarrhal pneumonia is a disease of much greater severity. It commences as bronchial catarrh, which rapidly spreads to the minute ramifications, producing abundant and sub-crepitous râles. After a few days consolidation occurs, giving rise to bronchial soufflé,

thus evidencing that the inflammation has reached the parenchyma of the lungs. The febrile excitement is not so great as in simple pneumonia, and is subject to partial remissions. The treatment in M. Trousseau's practice is most unsatisfactory, but he distinctly attributes this to the unfavourable conditions under which the patients are placed in the crowded wards of the hospital. In private practice the disease is far less formidable, and yields to a plan of treatment well understood in this country.

General Retrospect.

PRACTICAL MEDICINE.

Dilatation of the Common Bile-Duct.

A case, which is almost, if not quite, unique, is mentioned by Dr. Halliday Douglas, in which the common bile-duct became dilated to an enormous size. The patient, aged 17, was a servant, who was admitted with symptoms of jaundice, with pain on the right side of the abdomen, which was full and tender to the touch. She stated that her complaints had commenced three years previously, with frequent paroxysms of pain in the right hypochondrium.

The first of such paroxysms observed in the hospital was preceded by rigor, and followed by an increase in the fulness of the right side. Pulse 100. Tongue dry, and constipation obstinate. The pain lasted three days. Several other paroxysms occurred, but they were greatly diminished in intensity by blistering and enemata. Eventually the hypochondriac tumour became so prominent with fluctuation, that tapping was performed with immediate relief, but she daily lost ground, and died somewhat suddenly.

Post-mortem examination.—On opening the abdomen a large fluctuating sac was found occupying the whole right side, and closely connected with the liver. It contained half a gallon of yellow foetid fluid, having the consistence of thin syrup. The walls were dense and fibrous; the internal surface had also a fibrous appearance, and patches were seen of a pearly texture. In the upper part of the sac the orifices of the hepatic and cystic ducts were dilated, so as to admit the finger. The hepatic duct was dilated as far as its second and third divisions. After a careful search, an orifice was also found in the lower end of the sac, which opened into the continuation of the common duct. The fluid contained crystals of cholesterine.—*Monthly Journal of Medical Science*, February, 1852.

On Diseases of the Chest supervening on Accidents and Operations.—By Dr. BLAKISTON.

The object of the author's paper is to point out a fact, which cannot be too strongly impressed upon surgeons, viz.,—that most of the secondary inflammations with which they have to do, after operations and severe injuries, are of an asthenic character; and that they are caused by the depressing effects of the accident, combined with, to no small extent, in our belief, the low diet and regimen to which routine practice too

generally submits the patient. The forms of inflammation which the author mentions are,—pericarditis, pleuritis, pneumonia, and purulent deposits. Speaking of the prevention of these formidable consequences, the author alludes to the time when patients were prepared for operations by preliminary starvation and purging. Misled then, as too many surgeons are in the present day, by the term "inflammation," the operator was induced to adopt a lowering plan of treatment, little suspecting that the majority of inflammatory attacks were of a passive asthenic character. In the author's opinion the treatment best suited to ward off secondary chest affections is such as is calculated to preserve the health at its full standard; blood-letting being employed in a very guarded manner, giving the preference to local over general depletion; purgatives being given so as only gently to move the bowels; with well ventilated apartments and nutritious diet, and stimulants proportioned to the patient's previous habits, so that a healthy blood plasma may be formed, with little effort of the digestive organs.

A modification of this prophylactic treatment may be necessary in accidents to the head, with the prospect of acute meningitis, or in the case of acute pleuritis after fractured ribs; but here the author thinks general depletion is seldom called for, the preventive treatment consisting rather in the exhibition of mercury and local blood-letting.

In the treatment of these diseases, the author states that antimony is seldom so well borne as in primary pneumonia; and that mercury and opium should be our chief remedies, with wine and ammonia. So, too, in secondary pleurisy and pericarditis.—*Medical Times and Gazette*, Feb. 14, 1852.

SURGERY.

Treatment of Spermatorrhœa.

Mr. Henry Thompson has proposed a modification of Lallemand's caustic bougie, the application of which is in his opinion, uncertain as to its effects, often causing more irritation than is either requisite or innocuous. He suggests, in lieu of the solid caustic, the application of solutions of various strengths, by means of the instrument which he thus describes:—

It consists of a curved cannula, resembling a No. 9 or 10 cannula. Within this is a strong stilette, at one end of which is a well-fitted piston, while the other protrudes in the shape of a handle from the outer extremity of the cannula. Immediately below the piston is a piece of sponge an inch long, and fitting the cannula; at one end of this is an oval bulb forming the end of the cannula; at the other, nearest the piston, is a metallic plate.

This sponge is charged with the solution to be employed, and then drawn within the cannula. The instrument is then introduced as in the case of Lallemand's caustic holder, and when opposite the membranous portion of the urethra the sponge is again caused to protrude and rotated by a motion of the handle. It is again withdrawn into the cannula and the instrument is removed.—*Lancet*, Jan. 24.

[In the *Medical Times* of February 14th, the priority of claim to this invention is maintained

by Mr. H. Smith. We have frequently had occasion to prescribe the operation by means of Lallemand's instrument, and have never known any unpleasant consequences in properly qualified hands; we can, however, easily conceive that with incautious or inexperienced operators, Mr. Thompson's modification would be the safer resource.—*Ed. P. J.*]

Gastrotomy successfully Performed.

Three cases of this formidable operation are reported in the recent American journals.

In the *New Orleans Medical Journal* Dr. Boling relates a case of extra-uterine pregnancy in a negress, aged 28. The operation was successfully performed, and a seven months' foetus was extracted from the right Fallopian tube.

In a second case the foetus was hydrocephalic, and rupture of the uterus occurred, nevertheless the patient is said to have recovered.

The third instance was that of a negress in whom there was total occlusion of the os uteri. The Cæsarian section was preferred to incising the cervix, (why, it is not said,) and both mother and child were saved.—*American Journal of Medical Science*, Jan., 1852.

Cystic Bronchocele Cured by Injection with Iodine.

By JOHN HILTON, F.R.S.

The patient was a female, aged 26, presenting a large fluctuating swelling in the seat of the thyroid gland, and extending from the os hyoides to the sternum. It was tapped, and a considerable quantity of dark fluid was drawn off, which was found, under the microscope, to contain granular corpuscles, shrivelled blood discs, and plates of cholesterine. The tumour filled again, and was again emptied; but this time Mr. Hilton caused it to be injected with Tinct. Iodinii, dr. j.; Aquæ, dr. iij.

On the following day the swelling had much increased, and was hot and tender. The pulse became quick, the skin hot, and the tongue dry. During the succeeding week the constitutional symptoms became very threatening, and the swelling further increased in size. Vomiting also became an urgent symptom. Mr. Hilton now punctured the cyst with a lancet, and let out a quantity of gas, mixed with a very offensive sanious and purulent fluid. This gave great relief; and in a few days healthy suppuration became established. This ultimately disappeared, and a complete subsidence of the tumour was the fortunate result.—*Medical Times*, January 10, 1852.

MIDWIFERY.

Turning as a Substitute for Craniotomy.—By Professor SIMPSON.

The Edinburgh Professor of Midwifery has made his opinions familiar to our readers by a series of valuable papers which appeared in this journal, (1847—48); the subject is continued in the *Monthly Journal of Medical Science* by some further observations, the pith of which may be thus recapitulated:—

1. Turning substitutes delivery by the hand for the use of formidable instruments.
2. The transit of the cone-shaped head of the child

through a narrow brim is facilitated by the narrow end of the cone (the bimastoid diameter) being made first to enter the strait; and the hold obtained on the body of the child enables the engaged foetal head to be effectually compressed, so as to allow of its passage.

3. When the child is brought down footling, we have more power to adjust the shape of the head to the brim, than when the spherical arch of the cranium presents.

4. The *lateral* and *temporary* compression of the foetal head in the contracted brim which is produced during the operation of turning, is less dangerous to life than its *oblique* or longitudinal compression with the long forceps, or by the *long* impaction of the head itself.

5. In cases of still greater deformity, a degree of pressure, causing indentation of the cranium, if transient, is not necessarily destructive of life. Perforation of the head necessarily is so.

6. On these accounts turning offers a fair chance of life to the infant, while craniotomy affords none.

7. The operation of turning will also, Dr. Simpson believes, be found more safe to the mother than craniotomy. In every instance the latter is necessarily fatal to the infant, but in a large proportion of cases also it is fatal to the mother. Dr. Churchill's statistics give 1 death in 5 cases to the mother, while in version cases, even of a complicated nature, the deaths are but 1 in 15 or 16. It also affords this great source of safety to the mother, that turning would be adopted earlier in labour than craniotomy, and it is capable of demonstration that the maternal mortality is in direct ratio to the duration of labour.—*Monthly Journal of Medical Science*, February, 1852.

Correspondence.

ABSORPTION OF THE MAMMÆ AND TESTES UNDER THE USE OF IODINE.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—In reference to the interesting question, inserted in your journal by Mr. Gall, of Ripley,—Whether the use of iodine really produces wasting of the mammæ and testes, I beg to remark that I have prescribed the use of iodine, both internally and externally, in several cases of bronchocele, all of them in females; and that in four of these cases the internal administration of the remedy was carried to the extent of producing decided emaciation of the body generally. In these cases the breasts participated in the general wasting of the system: but *their true glandular structure remained unaffected*. On suspending the remedy the patients regained their plumpness, and the breasts recovered their former size. I can easily imagine that in these cases the mistake might have been made of supposing that there was wasting of the mammary glands, attributable to the use of iodine; but it was evident that the wasting of the mammæ was *apparent* only, from the absorption of some of the adipose tissue entering into their structure, and not *really* a *wasting of the organs from absorption of the glandular*

structure. This was my conviction from careful examinations, made in reference to the question at issue; and I have ever since entertained a suspicion of the correctness of the statement that iodine will cause wasting of the mammæ and testes, which appears to have obtained credence by most writers on materia medica and therapeutics. As far as the mammæ are concerned, the error may readily be accounted for by the *apparent* emaciation referred to. It is, perhaps, not so easy to account for the similar statement in regard to the testes, if it should be ascertained that these organs are really unaffected by the continued use of iodine, since they are not surrounded by adipose tissue, as are the mammary glands, and, therefore, could not be subjected to any *apparent* diminution of size in general emaciation of the system. All the cases of bronchocele under my treatment have been in the female; and I have not used iodine for any disease in the male to such an extent as to produce any wasting of the body, so that its effects upon the *testes* must be decided by the experience of other practitioners. Before leaving the subject, I would just remark that I have generally found the bronchocele reduced by the moderate internal and external use of iodine, without the necessity of pushing it to the extent of causing wasting of the body. Of the four cases referred to, two yielded to the remedy, but the other two were unaffected by the medicine, after persevering with it to the utmost limit of safety.

THE RECIPROCAL INFLUENCE OF PREGNANCY AND PULMONARY PHTHISIS.

The opinion is generally entertained that *pregnancy temporarily arrests the progress of phthisis, which, after delivery, then proceeds more rapidly to its termination*; but according to Dr. Grisolle (*Archives Générales de Médecine*, and quoted in the periscope of the *British and Foreign Medico-Chirurgical Review*, July, 1850,) this opinion is founded upon insufficient data; and he arrives at an opposite one from the consideration of twenty-seven cases, seventeen of which were under his own observation, and ten communicated to him by M. Louis.

It would appear that the number of cases adduced by Dr. Grisolle is too limited to decide this interesting question; and that the subject may with advantage be investigated on a large scale, and set at rest by the combined efforts of the members of this Association. If every member who may have taken notes of these cases will forward them to the *Journal*, and if each member will take special notice of the subject during the ensuing twelve months, particularly in reference to the subjoined questions, and will kindly forward the particulars to the *Journal*, I shall be happy to take charge of the subject, and, to the best of my ability, to collect and put into shape the facts communicated, with the view of permanently settling this doubted point of pathology.

Where it is practicable, it will be better to record the following facts; but should the questions be too numerous to be answered as a whole, I would urge upon the members of the Association to answer those directly bearing upon the *influence of pregnancy on the progress of pulmonary consumption*, and to leave the rest.

1. When did the signs of phthisis first appear ;—before or during the period of pregnancy ?
 2. Was hæmoptysis a symptom ?
 3. In how many months after the first appearance of the symptoms, and at what period after delivery, did death occur ?
 4. Has abortion (and at what period) occurred during the progress of phthisis ; and has the patient died in any case before the full period of pregnancy ?
 5. Has labour been difficult in any case during the progress of phthisis ; and was the child vigorous and full-sized ?
 6. Was the secretion of milk in due quantity ; and when did it diminish or cease ?
 7. What was the effect of suckling—1st, upon the mother ; 2nd, upon the child ?
 8. In *post-mortem* examinations were tubercles observed in the lungs of the child ?
 9. Where the auscultatory signs have been traced, what has been their progress during pregnancy ?
 10. Has any case occurred in which *unequivocal signs of phthisis existed at the period of conception*, and in which the symptoms have been *decidedly kept in check during the entire period of pregnancy*, manifesting themselves immediately after parturition, and going on uninterruptedly to a fatal termination ?
- Any other particulars not mentioned in these questions will be gladly received.

I am, Sir, your obedient Servant,

T. HERBERT BARKER, M.D.

Bedford, February 17, 1852.

THE NEW MEDICAL BILL.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—In answer to your repeated requests for individual expressions of opinion respecting the “New Medical Reform Bill,” I give you mine, individually unimportant enough, but worthy of publication, if they express, as I believe they do, the feelings of a very large body of medical men. I am sorry to see divisions and discussions on minor matters, or assertions that the new Act “will lower the profession.”

What is the present standard of professional character, that such fears are entertained of its being lowered ? Are there not names on the list of the College of Surgeons who advertise, who homœopathise, who will fawn and lie to gain a patient, or blacken the character of a professional brother. Are there not men whose ignorance is notorious, who have spent their years in idleness and drunkenness, yet who, after a careful grind, struggle through College and Hall ; and are not the town and country crowded with a large and increasing class of irregular practitioners, who, having failed to pass their examinations, or even having only acquired a smattering of medical knowledge, from spending a few years behind a druggist's counter, deal with the lives of their fellow-creatures as ignorant unprincipled adventurers may be supposed to do. We want, Sir, a law that will separate us from all these,

and ally us to a class of our profession who are an honour to England, and whose skill and honourable bearing, whose benevolence to the poor in their private practice, and whose expenditure of time and trouble in public charities, is unequalled by any other body of men in England, or, I believe, the world.

An Act of Parliament that provides for the expulsion from our body of men who have forfeited their character, that by frequent registration shows who *do* belong to us, and that provides an easy way of punishing those who practise without a qualification, and, lastly, that gives an examination not more difficult but more practical, must raise the profession ; and we ought, in the spirit of its proposers, to consider whether, by the alteration of any parts, it can be made more effectually to answer objects all have in view. Allow me to urge for these reasons a sacrifice of pet schemes and theories, and an unanimous approval of the chief features of the “New Medical Bill.”

I remain, Sir,

Your obedient Servant,

ALEX. H. PATERSON.

Altrincham, February 18, 1852.

To the Editors of the Provincial Medical and Surgical Journal.

GENTLEMEN,—I am desirous of offering my warmest thanks to the framers of the Medical Bill, for the zeal and judgment displayed by them, and in addition to the gratitude of the profession, which is eminently due to them for the service they have rendered, I trust they may be further rewarded by the measure quickly passing into a law.

I would submit the desirability of increasing the admission fee to practise to above £10. None of our medical corporations are wealthy in a pecuniary view, although the fee in some of them is higher than this, and I doubt very much whether all the good objects contemplated in the bill could be effected without a larger fund than could thus be raised.

I strongly approve of the annual renewal of the certificate and of the appropriation and amount of the fee by which the certificate is to be obtained.

The strictest possible penal measures should be adopted to prevent those from practising who have not obtained the licence to practise. It is not a proper argument against this that the Apothecaries' Company have failed in this object. Their law proceedings have hitherto been expensive, unwieldy, and of doubtful success, while the fine has been much too large. Moreover, the Company have brought disfavour on such efforts by generally selecting for their victims those who, although not possessing their licence, have in many cases received a regular professional education, while they have permitted the uneducated quacks and druggists to realize fortunes unmolested. The fine should be under £5, and the delinquent should be summoned before a magistrate by any informer, and summarily convicted. If this could not be carried out, the least that may be done is to fine any unlicensed person who *visits and prescribes* for a patient, while no debt contracted in such manner should be recoverable at law.

Trusting the profession may be unanimous in the support of a bill so greatly calculated to forward their interests and increase their political and professional status,

I remain, Gentlemen,

Very obediently yours,

PHILO.

ON THE

VARIETIES OF CRANIAL PRESENTATION.

To the Editors of the *Provincial Medical and Surgical Journal*.

GENTLEMEN,—In my paper which appeared in the last number of the *Journal*, I quoted some statistics of Dr. Simpson's in reference to the relative frequency of the different cranial presentations. These statistics were taken from a review of Dr. Miller's book "On Midwifery," in the *British and Foreign Medico-Chirurgical Review*. Dr. Simpson has since written to me on the subject, and has sent me a copy of the original pamphlet, from which the statistics mentioned in the review were taken. From this it appears that there has been some unaccountable error in the figures quoted in the *Review*. Thus it has been stated that the whole number of Dr. Simpson's cases was 668 instead of 335; also that there were 256 cases belonging to the second presentation instead of the first, and 76 cases belonging to the fourth instead of to the third; so that the results of Dr. Simpson's statistics corroborate those of the German accoucheurs instead of contradicting them. When I wrote my paper I had not seen these lectures of Dr. Simpson's, in consequence of their having been published some years ago, in the *Northern Journal of Medicine*, (which has since ceased to exist,) and I was thus led into the error which Dr. Simpson has kindly furnished me the means of correcting.

I am, Gentlemen,

Your obedient Servant,

J. G. SWAYNE.

12, York Place, Clifton,

February 25, 1852.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—Allow me to reply to Dr. Swayne's article "On the Varieties of Cranial Presentation," as he therein cites Dr. Simpson as an authority which will support his own views.

That he is in error will be at once apparent from the subjoined table, in which are given Dr. Swayne's statistics, (from his article,) and those of Dr. Simpson, as first published in the *Northern Journal of Medicine*, April, 1846, which have recently appeared in "Churchill's Manual," 1850, p. 165.

	Swayne.	Simpson.
1st position	247 in 286 or 86.3 per cent.	256 in 335 or 76.4 per cent.
2nd "	28 in 286 or 9.7 "	1 in 335 or 0.29 "
3rd "	3 in 286 or 1.0 "	76 in 335 or 22.7 "
4th "	8 in 286 or 2.7 "	2 in 335 or 0.58 "

I have, moreover, Dr. Simpson's authority for stating, that his experience up to the present time accords with

the above, as to the great preponderance (99 in 100) of the first and third positions; that the second and fourth rarely, if ever, occur, unless the head of the child be unusually small, or the pelvis of the mother unusually large, or some other abnormal condition be present,—*e. g.*, the passage of the rectum into the pelvis on the right side.

On further comparison of Dr. Swayne's letter with the article above referred to, I find that Dr. Simpson agrees with Naegelè on the frequency of rotation of the head of the foetus in occipito-posterior positions rather than with Dr. Swayne. In the seventy-six cases of the third position, rotation was observed in seventy-four; Naegelè observed it in ninety-three out of ninety-six cases.

We cannot, therefore, admit Dr. Swayne's conclusion, "that the difficulties which are said to attend such (occipito-posterior) positions are more theoretical than practical;" nor his explanation that they are believed in, "from making comparisons of dried pelves and crania." From such a mode of study we may indeed assume, that a head will pass where it is difficult and often impossible, as from the fourth position. Or, again, may be likely to agree with Dr. Swayne, that "the second presentation (position) is in every way similar to the first." But there is little danger of practical error in concluding that the same difficulties which oppose the ready passage of the dry head through the dry pelvis, exist in the recent pelvis where the bones are covered, and other organs *in situ*. We shall allow very little for "the very great alteration which may take place in the shape of a child's head during labour," if we rely on the experiments of Baudelocque, who found that compression of the head of a foetus to an extent greater than four lines produced fracture of the cranium, and that the force required was sufficient to bend a strong pair of forceps.

Dr. Swayne's method of diagnosis seems very simple. If others can confirm his observations in practice, (I have not at present the opportunity,) a notice to that effect in your journal would be valuable and a just acknowledgement to Dr. S., meanwhile the modes proposed by Dr. Simpson—the movements of the foetus, the sounds of the fetal heart, the tactile examination of the child's head—being independent, may be useful as a test.

Your obedient Servant,

WILLIAM OGLE.

Student of Medicine.

Edinburgh, 150, George Street,
February 25, 1852.

MR. HUGHES AND MR. NOBLE.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—In your publication of last week I find the same lengthy correspondence as appeared in the *Lancet* and *Medical Times and Gazette*, in which I am *courteously* described as a person notoriously disqualified. The facts are these:—I attended Mrs. O. C. in her confinement; all went on well for seven days, when she was suddenly attacked with symptoms of puerperal mania. A messenger was despatched to me in great haste, but did not

arrive or deliver the message. Mr. O. C., tired of waiting, consulted Mr. McG., a chemist and druggist, (Mr. Noble's Poor-law vaccinator,) hence Mr. N.'s visit, but I arrived at the house soon after Mr. Noble's departure. I beg to state that the *case* never was Mr. N.'s, (but indirectly.) Being of opinion that the case was of a more serious nature than what Mr. Noble represented it to be, I advised Mr. Windsor to be sent for, when her attendants sent for him, he not being aware of Mr. Noble having visited her previously.

Respecting my own qualifications, I would just add, that I have served a regular apprenticeship to the profession, and completed the full course of lectures required by the College of Surgeons, and I intend presenting myself for examination as soon as my circumstances will allow me to do so. The *Medical Times* states, that all persons practising as apothecaries without the Apothecaries' license are irregular practitioners. I am fully convinced that Mr. Noble is in the habit of meeting persons in consultation who have no legal medical qualifications.

I am, Sir, your obedient Servant,

WILLIAM HUGHES.

15, Chatham Street, Piccadilly, Manchester.

January 30, 1852.

Medical Intelligence.

MEDICAL BENEVOLENT FUND.

We are requested by Mr. Newnham to insert the following remarks on the Benevolent Fund and notice of the forthcoming dinner of this charity:—

This fund is truly catholic in its nature, its operation extending to the entire kingdom of Great Britain, and requiring only that the recipients of its bounty be regularly educated medical men or their families, and that they be in distress, and of good moral character.

It is not a provident society, in which a certain subscription constitutes a member, and membership gives a *claim* for relief; but it is purely a charitable institution, and extends its aid to every authenticated case of misery. It is the only society in the kingdom for the *immediate* relief of the temporary embarrassment of medical men, or for those frequent emergencies to which humanity must ever be liable, in spite of the utmost providence and foresight. Its benefits are conferred not simply on medical men themselves, but on their widows and orphans. The *aged* widows, too, are not forgotten, and annuities are granted to these, as circumstances admit, out of the income arising from the donation or accumulating fund; and in this way, wherever, from straitened circumstances, there is embarrassment—wherever sickness has deprived a family of the means of their support—wherever death has left a household in a state of destitution and helplessness, oftentimes in a state of starvation—wherever the sting of misery is to be assuaged, or the feeble efforts of penury are to be encouraged or sustained—and, finally, wherever the bed of death is to be softened, and the last hours of life are to be irradiated by the bright ray

of charity, there is the peculiar sphere of operation of the Medical Benevolent Fund.

London, 46, Princes Street, Soho.

Dear Sir,—I have the pleasure to inform you that the Right Honourable the Earl of Carlisle has consented to preside at the dinner in behalf of the Medical Benevolent Fund, to be held at the London Tavern, on Thursday, the 20th of May, 1852. The Committee will esteem it a favour if you will become a steward on that occasion. The expense is limited to a guinea, the price of a ticket.

I am, dear Sir,

Yours very faithfully,

W. NEWNHAM,

Treasurer and Honorary Secretary of the Fund.

P.S. The Treasurer requests that each individual subscriber will consider the above invitation as sent to himself, and will be obliged by a communication stating if it be the intention of the subscriber to honor the dinner with his presence; or, if without such intention, he would like to take a dinner ticket in aid of the charity.

W. NEWNHAM.

APPOINTMENTS.

Joseph Toynbee, Esq., has been elected Consulting Aural Surgeon to the Asylum for the Deaf and Dumb. It is, we believe, the largest establishment of the kind in the world. This is the first time that any surgeon has been appointed especially to examine the children in reference to their deaf-dumbness, and, we doubt not, that much good to the profession will result from this appointment.

Dr. Shaw, of the Bombay Medical Service, has been appointed Deputy Assay-Master at Madras.

ROYAL COLLEGE OF SURGEONS.

The examination of candidates for Fellowships, in classics, mathematics, and French, will be held in the first week in March, and the professional examination for Fellowships in the first week in April. The following will be the subjects of examination:—In Classics—Either of the following Greek and Latin authors—Herodotus, book 3; the Iliad, book 6; Virgil's *Æneid*, book 8; and Livy. In Mathematics—arithmetic, algebra, as far as to include the doctrine of proportions and simple equations, with one or two unknown quantities; Euclid, books 1, 2, and 3; hydrostatics, acoustics, and optics. In French—translations into English of passages from one of the French classical writers.

SOCIETY OF APOTHECARIES.

The following gentlemen were admitted members on Thursday, February 12;—William Maxwell Burham, Wath-upon-Deerne; John Kent Spender, Bath; James Strange Biggs, Devizes, Wilts.

The following gentlemen were also admitted members

on Thursday, February 19:—Thomas John Eames Brown, Dorchester, Dorset; George Samuel Rhodes, Dewsbury, Yorkshire.

NAVAL PROMOTION.

In consequence of the successful storming of Lagos, Mr. Frederick Foster Morgan, assistant-surgeon, has been promoted to the rank of surgeon. All the medical officers of the squadron were highly commended in the despatch received from Commodore Bruce.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

SOUTH WESTERN BRANCH.

A special meeting of the South-Western Branch of the Association, will be held on Wednesday, the 10th instant, at the Exeter Dispensary, to consider and discuss the "Draft Bill for Medical Reform," published in the *Journal* of the 21st of January last. The chair will be taken precisely at one o'clock, p.m.

W. D. KINGDON, M.D., Secretary.

Exeter, February 28, 1852.

YORKSHIRE BRANCH.

A SPECIAL meeting of the YORKSHIRE BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION, was held at the Philosophical Hall, Leeds, on February 26th, for the purpose of considering the "Draft of a Bill for Medical Reform." Present—Dr. Branson, of Sheffield, the President, in the chair; Dr. Chadwick, of Leeds; W. Hey, Esq., Leeds; Caleb Williams, Esq., York; H. Jackson, Esq., Sheffield; J. P. Garlick, Esq., Leeds; William Price, Esq., Leeds; S. Hey, Esq., Leeds; Thos. Nunneley, Esq., Leeds; J. Crosby, Esq., Great Ouseburn; J. I. Ikin, Esq., Leeds; J. Ellerton, Esq., Aberford; William Matterson, jun., Esq., York, Secretary.

After some interesting remarks from the Chairman, the following resolution, proposed by W. HEY, Esq., and seconded by Dr. CHADWICK, was carried unanimously:—

"That this meeting of the Yorkshire Branch of the Provincial Medical and Surgical Association, after carefully considering the Draft of the Bill presented to them by the Worcester Council, is of opinion that such Bill represents the general principles previously entertained and constantly advocated by the parent Association; but in order to secure for it the general support of the profession, several modifications in its details will have to be effected."

The meeting then proceeded to examine the several clauses of the Bill, and the following modifications were proposed and adopted, as suggestions for the consideration of the Central Council:—

Clause 3.—That after the appointment of the six members by the Apothecaries' Company, the succeeding appointments to fill up these vacancies as they arise shall be placed in the hands of the Home Secretary.

Clause 9.—That there shall be paid to the members of the several Councils such reasonable expenses incurred by the said members in the performance of their duties under this Act as shall from time to time be allowed by the said several Councils.

Clauses 11 and 12.—That three months instead of one month be adopted.

Clause 17.—That there be a fee, but that "20s." be omitted.

Clause 18.—That so much of the clause as follows the word "direct" be omitted; and that a portion of clause 19 be appended to it, omitting the Medical Provident Fund.

Clause 22.—There is an omission of other recognized Colleges in Scotland and Ireland.

Clause 23.—That surgical operations be inserted.

Clause 25.—That all unqualified persons be prevented giving evidence in Courts of Law.

Clause 34.—Not to omit other recognized Colleges in Scotland and Ireland.

Clause 39.—That it is questionable whether this clause should be retained.

WM. MATTERSON, JUN., Secretary.

York, February 27, 1852.

TO CORRESPONDENTS.

Communications have been received from Mr. Soden, Oculus Apertus, Medicus, Mr. Perceval, Mr. Collison, Mr. Foote, and Dr. Barker.

THE NEW EQUITABLE

LIFE-ASSURANCE COMPANY.

INCORPORATED BY ACT OF PARLIAMENT, 7 AND 8 VIC., CAP. 110.

TRUSTEES.

SIR JAMES DUKE, Bart., Alderman, M.P. for the City of London.
JAMES WYLD, Esq., M.P. for Bodmin.
WILLIAM FERGUSSON, Esq., F.R.S., Surgeon in Ordinary to H.R.H. Prince Albert; Professor of Surgery to King's College, London.

GEORGE JAMES GUTHRIE, Esq., F.R.S., late President of the Royal College of Surgeons; Consulting-Surgeon to the Westminster Hospital.
SIR CHARLES HASTINGS, M.D., Founder of the Provincial Medical and Surgical Association of England, and President of the Council.

DIRECTORS.

CHAIRMAN OF THE BOARD.

ROBERT LEE, M.D., F.R.S., Savile Row, Burlington Gardens.

DEPUTY CHAIRMAN.

GEORGE BEAMAN, Esq., M.R.C.S., King Street, Covent Garden, and Hampton Wick.

CONSULTING PHYSICIANS.

MARSHALL HALL, M.D., F.R.S., Grosvenor Street, Grosvenor Square.

CHARLES J. B. WILLIAMS, M.D., F.R.S., Holles Street, Cavendish Square.

JAS. ARTHUR WILSON, M.D., Dover Street, Piccadilly.

CONSULTING SURGEONS.

WILLIAM FERGUSSON, Esq., F.R.S., George Street, Hanover Square.

J. RANALD MARTIN, Esq., F.R.S., Grosvenor Street, Grosvenor Square.

SAMUEL SOLLY, Esq., F.R.S., St. Helen's Place, City.

SURGEON AND MEDICAL EXAMINER.

THOMAS WAKLEY, Esq., F.R.C.S., Guildford Street, Russell Square.

STANDING COUNSEL.

SIR ALEXANDER COCKBURN, Her Majesty's Attorney-General.

GEORGE WOODYATT HASTINGS, Esq., Paper Buildings, Temple.

SOLICITORS.

Messrs. **BELL, STEWARD, and LLOYD**, 59, Lincoln's-inn-fields.

BANKERS.

THE COMMERCIAL BANK OF LONDON.

SECRETARY.

H. BARBER BEAUMONT, Esq.

CONSTITUTION AND REGULATIONS OF THE COMPANY.

CAPITAL.—MUTUAL ASSURANCE.

The "NEW EQUITABLE" embraces all the advantages of a strictly Mutual Office, with the addition of an ample subscribed paid-up capital, forming a *bond fide* security for its policy-holders.

POLICIES INDISPUTABLE.

The Policies of this Company being Indisputable, they become as readily negociable, in monetary transactions, as any other description of personal property.

SPECIAL ASSURANCES.

All the different varieties of Life Contingencies may be provided against by Assurances in the New Equitable; and every accommodation is granted to the Assured for payment of premium.

INVALID LIVES

Are assured at rates adapted to the circumstances of each case. Every circumstance affecting the health impartially considered.

DIVISION AND APPROPRIATION OF PROFITS.

The whole of the Profits will be Equitably Divided amongst the holders of Policies issued on the participating scale.

MEDICAL PRACTITIONERS.

The Directors feel strongly that Medical Practitioners have not hitherto received that recognition, by Assurance Companies, which their professional knowledge, position, and valuable services entitled them to expect. They have determined, therefore, to frankly acknowledge and consult all duly qualified Medical Referees as the Medical Advisers of the Company, and uniformly transmit, with the Questions intended to be made the basis of every Official Medical Report, A CONSULTATION FEE OF TWO GUINEAS.

ANNUITIES AND ENDOWMENTS GRANTED.

Any further information may be had on applying personally, or by letter, to the Resident Director or Secretary.

CHIEF OFFICES—WEST STRAND, CHARING CROSS, LONDON.

MEDICAL BENEVOLENT COLLEGE.

ESTABLISHED JUNE, 1851.

PRESIDENT.

THE EARL MANVERS.

The THIRD LIST will be published at an early period.

Gentlemen desirous of acting as Honorary Local Secretaries will please forward their names to the office.

Further information may be obtained by addressing the Honorary Secretary, Henry Tudor Davies, Esq., 4, Hanover Square, where Subscriptions will be received, as well as by the Treasurer and the following Bankers:—Goslings and Sharpe, 19, Fleet Street; Coutts and Co., 59, Strand; Drummonds, Charing Cross; Glyn and Co., 67, Lombard Street; Scott and Co., 1, Cavendish Square; Messrs. Herries, St. James's Street; Messrs. Hoare, Fleet Street; the Union Bank of London, Regent Street, Branch; and by Cunliffe and Co., Manchester.

By order of the Council,

Office, 4, Hanover Square, Jan. 21, 1852.

HENRY TUDOR DAVIES, Honorary Secretary.

TO THE MEDICAL PROFESSION

AND OTHERS REQUIRING THE COMFORT OF AN ECONOMICAL
CLOSE CARRIAGE.

MESSRS. KINDER & Co., COACH BUILDERS,
OF WORCESTER AND MALVERN, in the
hope of securing a large number of Orders, are induced
to offer very superior BROUGHAMS, suitable for
Professional or Family Use, at an extremely low price,
and warranted of the best quality.

May be seen at their Manufactory, Tything, Wor-
cester; or full Particulars, with Drawings, forwarded
by Post on Application.

ON THE VIRTUES OF KOUSSO.

By W. BUDD, M.D.,

PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY.

To the Editor of the *Provincial Medical and Surgical Journal*.

SIR,—The best thanks of your readers are, I think, due to my friend and colleague, Mr. Prichard, for the very interesting accounts of koussou and its anthelmintic uses, which he has lately extracted, for their advantage, from the time-worn pages of Bruce and Ludolphus. (*Vide Provincial Medical and Surgical Journal* for January 21, 1852.)

As recording the testimony of two very remarkable men, whose travels in Abyssinnia lay more than a century apart, these accounts possess a lasting value. On close examination, it may, however, be doubted whether they warrant the inferences which at first view they seem to suggest, to the discredit of koussou as a remedy for worms in general, and for tape-worm in particular. I have, myself, given the koussou, now, in a considerable number of instances of tape-worm, and the result has been, with two or three exceptions, the expulsion of the worm, *including its head*, within a few hours of the administration of the drug. In the greater number of cases, too, the happy riddance has been effected at the cost of little or no pain, or other inconvenience to the subject of the parasite. Now, this is, presumably, all we are entitled to expect, or can reasonably hope to obtain, from a vermifuge, whatever its nature. It may not be out of place to add, that having at different times given a pretty extensive trial to various other remedies, among which I may mention turpentine, the æthereal oil of male fern, and the bark of the root of the pomegranate, I have found the koussou to surpass them all. If my experience in the matter may be trusted, koussou is at once more fatal to the worm, and less hurtful to *man*, than any of these medicines.

The following, among many others of which I have preserved notes, are good illustrations of its power, and as they present some other points of interest, you will, perhaps, give them a place in the *Journal*.

I remain, Sir,

Your obedient Servant,

WILLIAM BUDD.

28, Park Street, Bristol.

March 3, 1852.

CASE I.

MARY MCGOWEN, aged 48, a spare and emaciated-looking woman, and the mother of six children, was admitted to the Bristol Royal Infirmary on the 4th of October, 1850, for the cure of tape-worm.

First discovered that she was voiding joints of tape-worm *eighteen or twenty years ago*; has been infested with the parasite ever since, and although she has not had any acute or severe illness in the interval, her general health has much suffered in consequence. Has lived for many years past in a house in Pennywell

Road, but lived in Castle Street when the worm first made its appearance.

Chief Symptoms.—Habitual looseness of bowels; gnawing pain, with a sense of sinking at the pit of the stomach; a tendency to faintness; drowsiness; a sensation as of something twisting and rolling within the belly; itching at the nose, and similar but less urgent itching at the anus; winter cough, with profuse yellow expectoration, and, of late, great and progressive wasting. (When this woman first came under my care, these last features of her case were so strongly marked that, attended as they were by diarrhoea, it was only by repeated and careful examinations of the chest that I satisfied myself she was not *phthisical*.)

Has taken turpentine in large doses on at least twelve different occasions. The general result has been the discharge of a considerable length of worm, but the head has never been forthcoming, or, at any rate, has never been found, although always carefully sought for. Has also taken bark of *pomegranate root*, both in powder and in decoction, several times, but with still less effect.

On the 6th of October, after a twelve hours' rigid fast, and the bowels having been previously well cleared out by castor oil, koussou was administered in the usual fashion at eight in the morning. In the afternoon, the bowels not having acted, another dose of castor oil was given. In about an hour after a tape-worm was voided, *including the head*. It measured ten yards. It was remarked that the broad part of the worm showed a little movement for a short time after its expulsion.

The koussou caused no griping or other uneasiness, but there was a good deal of *internal commotion* for an hour or two before the worm came away.

On my seeing this woman some months afterwards, she had grown so fat, and was so much improved in appearance, that I scarcely knew her. She had seen nothing more of her old enemy; although from the circumstances in which she was living, the wonder rather was that she had not again become infested.

To the preceding history I have now to add the interesting fact that this parasite has fed on the chyle of, at least, three successive generations of this family. Mary Mc.Gowan's mother fostered a tape-worm for many years, and two of her children have succeeded to the same unenviable distinction. The worm has become a sort of heir-loom to the family. Soon after her own cure, the mother brought one of these children to me, and also some fragments of worm which the child had discharged the same morning. It is important to bear in mind that these children were both born after the removal of the mother to Pennywell Road.

Facts of a similar order will appear in the succeeding narratives. To those who have seen much of tape-worm, they will be no novelty, but they are so interesting in relation to the propagation of this creature, that they are worthy of especial mention.

Another fact of interest, in many ways, in Mary McGowen's case, was the great length of time during

which her intestines had been tenanted by the worm. For eighteen or twenty years fragments had been passing from her at short intervals. One is naturally curious to know whether this long period represents the life of a single individual, or the aggregate lives of several successors. This question, interesting as it may be, is one which we cannot hope to solve by direct observation. Probabilities would seem to be in favour of the latter view. Twenty years seem, at any rate, a monstrous longevity to assume for so simple and so prolific an organism. Under either view, when one thinks of the countless myriads of ova which must have been discharged from this woman in the course of that time, one cannot fail to be struck with the prodigal nature of the provisions made in the occurrence of every single instance for the maintenance of the species. The greater number of these ova were, no doubt, only cast off to perish; but we, also, have the case of the children to show, that by channels of which we can only guess, and under forms of which we as yet know nothing, but by sure and appointed methods, some among them had again found their way back to the human intestine.

In the following case the koussou was equally effectual, at the cost of as little inconvenience to the patient.

CASE II.

Frederick Powell, aged 17, a pallid but well-grown lad, was admitted into the Bristol Royal Infirmary, on the 15th of May, 1850, suffering under a painful condition of the legs, which were also thickly sprinkled with pale purpuric spots. On the 26th of May he became affected with acute rheumatism, which proved very severe, and was attended with endo-pericarditis. During his convalescence it was accidentally discovered that he was passing fragments of tape-worm. Nothing before had ever led him to suspect that he harboured this parasite, *although one of his elder brothers had been infested with it for some years*. According to his own report he had always enjoyed good health, had not been subject to loose bowels, and had never noticed itching of the nose, pain of the belly, drowsiness, or any of the other symptoms, common in persons infested with worms.

On the 16th of July, after two days low diet and a twelve hour's rigid fast, the bowels having been previously well cleared out by castor oil, a full dose of koussou was given at a quarter before nine in the morning. It did not cause nausea, nor with the exception of a slight bitterness in the mouth, any other disagreeable sensation. At a quarter-past one he voided the worm *including its head*, in a copious loose stool. The bowels acted once afterwards on that day, but no more fragments of worm were passed, nor could any be discovered in several copious evacuations which were procured the following day by the administration of a full dose of castor oil. The operation of the koussou was not attended by griping or any other unpleasant feeling. It may be worth remarking, that a few weeks afterwards, *two persons living in the same locality*, moved by the report of this cure, applied to me in the hope of getting

quit of their "familiar" on the same easy terms. I have also, since then, had several other instances of tape-worm from the same immediate neighbourhood.

CASE III.

The next case is that of a gentleman who had been harassed by tape-worm for many years, and who, at my suggestion, purchased in Paris, on his road to Naples, the facile means of its expulsion. The result is recorded in the following brief note from himself, written about a month after reaching his destination:—

"The second morning after my arrival, I took the koussou, and in less than one hour and a half after, and without the slightest pain or inconvenience, I got quit of my internal monster, about forty feet long and one third of an inch wide. I now feel quite another man, and have a voracious appetite. The koussou is a wonderful medicine, truly, and should be made universally known."

Although this gentleman does not specially mention the expulsion *of the head*, the fact recently communicated to me, that he has seen nothing more of the worm, may be taken as pretty sure evidence that this was effected. I might add many more such cases in proof of the easy and effectual operation of this remarkable remedy, but with the large body of evidence already on record to the same effect, these are perhaps more than enough.

It will be better in all ways, and certainly more candid, to close the list with a case in which the koussou failed.

CASE IV.

Eliza Powell, about 40 years old, was admitted to the Bristol Royal Infirmary, on the 3rd of July, 1851, to be treated for tape-worm, with which she had been infested for a period of six years. From the sequel there might have been some doubt that she still harboured the worm, had she not brought with her to the hospital about a week before her admission, some fragments which she had voided the same morning. She had taken turpentine on many previous occasions, but always without effect.

On the day of her admission she took three grains of calomel, and five grains of colocynth, followed by castor oil, by which she was freely purged.

On the following morning the koussou was given in the usual manner; but being vomitted soon after it was taken, was followed by no result. After waiting a day in order to recover the tone of the stomach, it was given a second time after the same manner; but although it was now retained, it did not cause the expulsion of a single fragment of worm! It is proper to add, that the æthereal oil of male fern was administered on two subsequent occasions with the same entirely negative result.

Such cases as these are rare, but were they much more common, they would not prove that koussou is not a remedy for tape-worm, but only that it is not *infallible*. That it should be so would be scarcely reasonable to

expect. Excluding the fact that this, like other drugs, is liable to *spoil*, even where ascertained to be genuine, there is every reason to suppose that the worm itself may vary much in tenacity of life, according to its *age*, to the periods of special activity or otherwise, in the generative function, and other conditions less easy to define. That many cases of failure have to be thus explained would appear from the fact that where the koussou fails, the subsequent administration of other anthelmintics is generally found to be equally unsuccessful.

It would be difficult to add anything to what has already been suggested by others with the view the better to insure the action of the drug. A preliminary fast, and a purgative to clear the bowels well out, so as to lay the worm bare to the action of the poison, are measures of which the motives are too obvious to need to be specially enforced. It is probable, however, that the choice of means for the latter object is not a matter of indifference. Of all these means, castor oil is perhaps the best. More drastic purgatives, without adding anything to the efficacy of the vermifuge, tend to make the stomach intolerant of its presence. A course of quinine or some other bitter medicine, for a week or ten days before giving the specific, seems, by lowering the health of the worm, to render it a more easy victim. It is an old observation, as the name of one of our garden herbs testifies,—that worms generally, are intolerant of *bitters*.

Finally, my own experience entirely confirms that of others, to the effect that all remedies are more deadly to tape-worm at those times (which recur more or less periodically,) when the animal is spontaneously shedding joints.

These are, in effect, as the fact itself shows, times of especial activity in the work of impregnation and maturation, and it is consistent with all analogy as well as reason, to suppose that this process is a cause of weakness and exhaustion to the parent.

If all the conditions here enumerated be well fulfilled, and if the drug itself be good and genuine, there is experience enough to show that the cases will be comparatively few in which its administration will not be speedily followed by the expulsion of the parasite. But, admitting all this, it appears from other considerations to be equally certain, that in whatever abundance nature may supply the plant, its employment cannot insure us against the return of tape-worm in the same individual, and still less provides the means for the extermination of this or any other species of worm among any given people. This would seem probable on the most general grounds, and is entirely borne out by what experience has taught us in parallel cases. Sulphur has long been known as a specific for itch, but itch, although less common, perhaps, than in the days of King James, is, nevertheless, far from extinct. In all matters of this kind we are naturally prone to judge *ex analogiâ hominis* instead of *ex analogiâ universi*. The more we reflect on the subject under the larger view, and, it may be added, the greater the amount of direct experience we accumulate upon it, the more

evident it becomes how very difficult it is to defeat the wonderful but unerring provisions by which the continuance of living species is maintained, in spite of the enemies by which all species are surrounded. Not only is this as true of the lowest and meanest parasite as of the highest order of creatures, but the lower the type the greater the difficulty becomes. Especially greater must it be, therefore, in the case of these intestinal worms, which, with the exception, perhaps, of certain fishes, possess a fertility which is unknown elsewhere in the animal kingdom.

Eshricht computed that a single specimen of the common *ascaris lumbricoides* contained 64,000,000 eggs. The tape-worm is immeasurably more prolific still. According to Professor Owen the *tania solium* and the *bothriocephalus latus* present a more extensive development and preponderance of the generative system than is to be found in any other living animal; in fact, he says, (and the observation is one which any one may readily make for himself,) “there is scarcely space left in the hinder joints of the tape-worm for the organs of any of the other systems.”

We have only to consider, in addition to the countless numbers of these ova, their hard crusts and shells, and their wonderful tenacity of latent life, to see what large conditions the extermination of this worm implies. How utterly inadequate the koussou must be to such a work as this, becomes still further evident when we reflect that, poisonous as experience has shown this plant to be, to the *head* of the tape-worm, there is nothing to show that it has any similar power over the *egg*. From the wide difference between the organization of these two parts, and, still more, from the care with which (if one may so speak) the egg has been guarded by peculiar and special provisions from the action of noxious agents, there is every reason to suppose that the drug is harmless to it. So that, (assuming this to be the case,) in the very act of destruction, the dead worm carries with it to its grave the spawn of a thousand successors. To speak the truth, however, the case as here stated is still short of the fact. Koussou is seldom taken, even I presume in Abyssinnia, until worms have given by their presence in the intestinal discharges, the only sure presumption of their existence in the intestine of the infested subject. By the very act, therefore, which leads to the administration of the specific, the casting out, namely, of myriads of mature ova, the parasite has already provided the conditions for its future propagation.

To look for the extermination of a creature multiplying by methods such as these, at the hands of an agent which only kills the individual worm, would be about as reasonable as to look for the extermination of thistles by rooting up the plant after it has cast its seed. It is of little avail to slay the dragon, if you sow the dragon's teeth.

It is scarcely necessary to remind those who have studied the subject as naturalists, that the extrusion of these ova is necessary to carry forward the work of propagation. It is not in their nature to grow up in the place of their birth to the likeness of their parent.

If, for this end, the remote offspring of these ova must again find their way back at some future period to the human intestine, it is equally necessary to the early phases of that cycle of development by which this comes to pass, that they should be first cast out into other media.

In the case of tape-worm the periodical shedding and discharge of joints in a state of maturation, and laden with ova, specially protected by hard crusts from all common causes of destruction, would be of itself, even were there no other evidence, all but sufficient to prove this. Under any other view we should have to suppose that the great function which well nigh monopolises the substance of the animal, and which seems to be the chief purpose of its life, is a function without object.

Again, if the ova had the capacity to grow up into the perfect worm, without leaving their first nidus, it would be impossible to conceive that tape-worm should ever be as in the rule we find it, and as its designation bespeaks, a solitary animal. Countless swarms on the contrary, should then have peopled the intestine. I believe I am correct in saying that the intermediate forms through which the egg passes in its transit back to its original *habitat* are at present unknown. From recent discoveries in neighbouring fields we may conjecture that they are neither few nor simple. That they must deviate widely from the parent type is plain enough.* These are, however, questions which concern the naturalist more than the physician, and are, besides, foreign to the object of this communication. Otherwise it would have been easy to show that facts like those recorded in some of the preceding histories—and I may mention especially that of Mary McGowen and her children—might be of some value to the investigation. It must not be supposed that such facts are exceptional. On the contrary, in so far as they are examples of cases of tape-worm occurring in groups, they only express the result of general experience. I could easily point out particular districts in Bristol where tape-worm is endemic. Indeed it seldom occurs to me to succeed in procuring the expulsion of one of these parasites without receiving soon after many applications from other sufferers from the same immediate neighbourhood, and it is by no means rare to meet with two or three infested persons from among members of the same household.

* Unfortunately, from the very nature of the case, the details of the migration, considered as an object of natural history, hardly admit of being directly followed out. It has occurred to me, however, whether the difficulties which lie in the way of direct observation might not be got over by experiment. By placing fragments of tape-worm laden with mature ova in conditions closely imitating those into which they pass in the common course of things, it might be possible to nurse some of these ova into higher forms, and thus to supply some of the links which connect them with the future worm. The inquiry is not, it must be owned, either savoury or inviting, but the interest of the results in view would probably more than repay the trials of the investigation.

CASE OF ILEUS WITH LONG-CONTINUED OBSTRUCTION.

By JOHN SODEN, Esq., F.R.C.S.,

SURGEON TO THE BATH GENERAL HOSPITAL.

Read at the Quarterly Meeting of the Bath and Bristol Branch, Dec. 17, 1851.

THE subject of the following case is a gentleman about 63 years of age, short in stature, of a nervous sanguine temperament, and of active and extremely temperate habits. For the last twenty years he has enjoyed uninterrupted good health; he had previously suffered from the effects of hot climate in the West Indies.

On October 16th, 1851, feeling indisposed, and for a short time previously his digestion having been out of order, he took an active aperient. It affected him with unusual severity, continuing in operation till the morning of the following day. He was then sufficiently well to occupy himself in his garden, where he was sometimes engaged standing about and assisting in planting. At dinner he eat a small quantity of meat. Soon afterwards he was seized with violent spasmodic pain in the abdomen. He took a large dose of castor oil with a few drops of laudanum, but ineffectually; an emetic of ipecacuanha was then tried with no better result. There was no disposition to sickness and the emetic action was not easily induced. An enema of warm water and a warm hip-bath were next had recourse to, but with no immediate relief. Towards evening, however, he became gradually better, and passed a tolerable night. On the following morning the pain returned with the same severity, and I then saw him for the first time.

This was on the 18th. I found my patient in an alarming condition. There was now frequent vomiting, the matters ejected being of a dark colour and very offensive, as was also the breath.

The attacks of spasm were intense; there was an anxious expression of countenance, and prostration of the nervous power seemed already impending. On examination there was a general sense of tenderness about the umbilicus, and chiefly on the left side, attended in this position by marked dullness on percussion; however, neither the dullness nor the tenderness were sufficiently circumscribed to indicate the precise seat of the constriction, supposing such to exist. I should mention that the patient was the subject of an inguinal hernia, and, that in spite of the large dose of oil (one ounce) that had been administered, there had been no passage from the bowels since the commencement of the attack. Uncertain whether I had to deal with an internal hernia or an attack of ileus, I at once determined to abstain from all aperient medicine, and I prescribed small doses of calomel and opium to be administered every two hours. Mustard poultices, and such other local means were used as seemed to afford alleviation. In the evening he was no better, and the ejections were now of a most suspicious appearance. I directed the pills to be continued, with an increased

quantity of opium. I was also induced to try the effect of a turpentine enema.

19th.—There is no amendment, but rather an aggravation of the symptoms, with the addition of hiccough. The enema was retained for some time, but returned unmixed with fæces, and without producing any sensible effect. The matters vomited are now purely fæcal. The countenance is more sunk, the prostration very great, and the case presents altogether the worst possible aspect.

I felt that there was nothing more to be done in the way of active means, and that it would not be prudent to carry the mercurial action further, though the pills had appeared to agree in invariably prolonging after each dose the interval from spasm and vomiting. I now purposed to administer one more opiate without the calomel, and then to strictly follow out the expectant course of treatment, not allowing anything to go into the stomach, and to abide the issue. I should mention, that early in the morning I had made another trial with the injection. I passed a long flexible tube into the bowel, to the extent of about twelve inches, and threw up as much warm water as the patient could bear, trusting, that if the disease arose from any mechanical cause, some relief might be afforded by this measure. The operation was effected without any difficulty or distress to the patient beyond the inconvenience of the distension of the bowel, but no result ensued; the water came away perfectly clear.

Before putting in force the plan of treatment I have indicated, I requested a consultation, and Mr. Gore was called in. Mr. Gore saw the patient with me between two and three P.M., nearly forty-eight hours from the commencement of the attack. He entertained a most unfavourable view of the case; his impression was against the idea of an internal strangulation from a mechanical cause, and he rather considered that the symptoms indicated an inflammatory state, of a low type, of some portion of the bowel, but that any opinion on the point could only be speculative and most uncertain.

Up to this moment there had been no reaction of a febrile character; the skin had remained cool throughout; the pulse very low but not rapid; the general symptoms had been those of a steadily progressing exhaustion. The powers were so low and the disposition to sickness so frequent, that Mr. Gore thought the effect of the opiate I had proposed would be doubtful, and that the safer course would be to follow out the expectant plan, without its administration. He also suggested that a drop of Scheele's prussic acid should be occasionally administered, and that instead of cooling the mouth from time to time with cold liquids, the patient should be permitted to suck a lump of cold ice.

20th.—On visiting my patient early this morning, I was glad to find him still alive and apparently in much the same state. The ice was most grateful to him, and he also found a soothing influence from the prussic acid. Whether it was really of any use, or whether the pleasurable sensation was attributable to the teaspoonful of cold water in which it was exhibited, I could not determine.

The vomiting continues at the same intervals; it is much less in quantity, from the empty condition in which the stomach has been kept, but still stercoraceous. The spasms have decidedly abated both in frequency and force. The same treatment to be steadily continued.

21st.—The vomiting has not been stercoraceous since last evening; the symptoms are all materially lessened, but great exhaustion is present.

7 P.M.—Great restlessness; voice weak and husky; throwing about of the arms. With these warnings I considered it absolutely necessary to administer some nourishment, and I commenced with a little barley-water and gruel.

22nd.—No return of vomiting; the small quantity of gruel taken has been borne, and the patient is not weaker to-day.

23rd.—Scarcely anything was swallowed yesterday; this morning's report is still favourable as far as relates to the local symptoms, and the abdomen, which has never been inordinately distended, is now perfectly flat; the signs of increasing debility are again more evident, and, in addition, there is some excitement of the head, heat and flushing, with a disposition to be talkative, verging on delirium. A very few teaspoonfuls of chicken broth to be occasionally administered.

24th.—Much the same; the same plan to be continued.

25th.—The excitement continues rather distressingly, with craving for food, and for some hours broth and arrowroot have been taken much more freely, the consequence is, fulness in the epigastrium, sense of sickness, and return of pain. It is evident that nothing can pass through the bowel.

26th.—To my surprise the patient is much improved this morning; free vomiting, which is not stercoraceous, has relieved the distress of yesterday; he is calm, and free from pain, but greatly exhausted. He is now sufficiently collected to be made aware of the importance of his abstaining from every kind of food, and with great resolution is determined to submit to that privation, or to any other treatment that may be proposed. The only chance seems to be to support life by injections. The plan has not hitherto been adopted, from the patient's excited condition, and his strong objection on account of painful piles, and a difficulty that he is now experiencing in passing water, and for the last few days he has not been in a state to be reasoned with on the subject. Half a pint of strong beef-tea, with four drops of laudanum, to be administered per anum, twice or three times a day. The ice and prussic acid, which are still very grateful, to be continued.

30th.—The injections have been regularly administered, and have answered admirably; they have never returned. There has been neither pain nor sickness, and the small quantity of laudanum appears to have exerted a general soothing influence. The patient's aspect is improved, and in point of strength he does not lose ground, though the rule of abstinence has been rigidly maintained. There is also further evidence of amendment, if it may be trusted. At six o'clock this morning the bowels were moved for the first time from the

commencement of the attack, on the 17th of October, thirteen days ago; the stool is liquid, small in quantity, and healthy in appearance. The treatment to be continued.

November 1st.—The bowels have again acted this morning, and the character of the evacuation leaves no doubt that it cannot have been merely the accumulated contents of the rectum from the injections.

From this date the case was straightforward. The utmost caution was pursued in the administration of food, and no relapse interfered with a gradual and progressive convalescence.

The attention of the profession has latterly been much directed towards cases of this description, with a view to their relief by operative means, where the symptoms appear to depend on mechanical causes. It would be a great boon if some clear diagnostic sign of distinction could be shown to exist between the effects of an internal strangulation, and the paralysis induced in its functions by an inflamed condition of a portion of the bowel. I fear the case I have just read will not tend to elucidate this difficulty. From reviewing the history of my patient's malady, I am totally at a loss to say in what it differs from those of persons in whom some accidental stricture was proved to exist. In cases of the latter kind the pain and tenderness may sometimes be more definite, but this is by no means a rule. There is nothing to be observed in the more tardy or violent onset of the symptoms; in both they come on with equal violence, and with equally rapid effect upon the powers of life. In both there is the permanence of the prostration so long as the bowel is impervious, and the continued absence of reactionary fever. Trace the individual signs, the flatulence, the character of the spasms, the hiccough, the stercoraceous vomiting, &c., and the analogy becomes only the more complete.

I have, therefore, I regret to say, no other practical deduction to bring forward than the testimony this case affords, of the favourable result that sometimes attends the resources of nature in cases of intestinal obstruction where art is of no avail.

NOTES

ON THE

TREATMENT OF CURABLE DISEASES.*

By W. S. OKE, M.D.,

Extra-Licentiate of the Royal College of Physicians, Physician to the Royal South Hants Infirmary, &c.

PORRIGO SCUTULATA. (RINGWORM.)

RINGWORM is primarily a local disease, appearing in annular patches. It most frequently infests the scalp, although it sometimes occurs also on other parts of the surface of the body, where the rings are generally of a

larger size. This disease is of a contagious character, and hence when it commences in a community of children, such as a school, it hardly ever fails to infect the whole establishment, through the medium of hats, caps, combs, &c., or by contact.

When this kind of porrigo takes place upon any part of the surface not covered with hair, it is easily recognised, and can be at once destroyed by the application of lunar caustic; and doubtless the same remedy would be equally successful on the scalp, but it generally happens that in such a hiding place, before the medical attendant is called in to take charge of the case, the disease has got possession of an extensive portion of the cranial region, and often, for a length of time, bids defiance to medical skill.

When porrigo scutulata is first discovered upon the scalp, the whole of the hair should be carefully, and as closely as possible, clipped off, in order to ascertain the extent of the disease; and should there be only a few patches, they should be touched with the nitrate of silver, wetted with water, every other day.

If the scalp be extensively affected, the lotion (1) may be substituted, and applied with a camel's hair brush. I have seen instances of the eruption exceeding the boundary of the hair, and reddening a considerable portion of the skin of the forehead, in which a solution of the chloride of lime was successful, although the cases were of long standing, as in 2.

Aque Puræ, oz. ij.

Misce fiat lotio bis quotidie bene applicanda.

When the disease has degenerated into an inveterate character, with acrid favi involving the follicles of the hairs, it becomes most obstinate, resisting almost every remedy; but even in this state the disease may sometimes be removed by the alkaline lotion

ECZEMA OF THE LEGS.

This kind of eczema is generally met with in elderly persons after the age of 50 years, and often occupies the whole or greater part of the space between the knees and ankles. In the acute form the skin is of a bright red colour, but when it has become chronic, it assumes a venous or purple hue. There is, in most cases, a profuse serous discharge from the vesicles,

* Continued from page 32.

which thickens, and forms scabs, and, as these are loosened by the continued discharge beneath them, they fall off, leaving the surface of the leg painful and raw till it scabs over again in the same manner. The legs are somewhat swollen, and the ankles and feet more or less oedematous.

Unless the constant irritation and pain attending the disease prevent sleep, the system is not much disturbed, indeed it may be sometimes relieved by the outbreak. Various local remedies have been used for the cure of this eruption, in the way of ointments, fomentations, lotions, &c., but most of these rather aggravate than relieve it, and cannot be borne long. The application which I have found most beneficial, is a bread-and-water poultice, with its surface spread with the *fresh* ointment of elder-flowers.

Case.—A clergyman, of delicate habit, and upwards of 70 years of age, became affected with eczema on both legs to a considerable extent. He was treated with various remedies, both internal and external, but all were unavailing, and appeared to increase rather than diminish the pain and irritation. His legs were red and swollen, and his feet oedematous. He could get no sleep, his appetite failed, the circulation was feeble, and he became alarmingly debilitated. Under these circumstances I resolved to wrap each leg in a large and smooth bread-and-water poultice, having its surface smeared with fresh elder-flower ointment, and repeated twice a day. It was at once evident that this was the remedy. The application was felt to be comfortable; the pain and irritation soon ceased, and allowed him to take rest; his appetite returned, and his general health improved. By continuing the poultices the inflammation of the legs, and the oedematous state of the feet, rapidly subsided, and in about a fortnight the treatment was attended with complete success.

The good effect of a poultice very much depends upon the way in which it is made. It should be prepared in the following manner:—Crumble a sufficient quantity of white bread, as finely as possible, into a good sized basin; then add boiling water, by little and little, and at the same time stir and mix the mass with a wooden spoon till it becomes a soft pulp. The poultice is to be spread on a napkin, or on linen cloth, about a third of an inch deep, and of an equal thickness throughout. Fresh elder-flower ointment, or whatever unctuous matter is made use of, should be smeared upon its surface, which will keep the poultice moist, and prevent it from adhering to the skin. When sores on the skin are of an irritating character, fresh ointment, made with elder-flowers, will be found to add to the soothing property of a poultice, but if not recent, it will become an irritant, and aggravate the disease.

If the eczematous outbreak take place in a full habit, the pill (1) and the mixture (2) will sometimes greatly conduce to its removal.

Aquæ Destillatæ, oz., v.

Misce Cap. cochlearia larga duo omni mane et meridiæ.

The Plummer's pill should always be taken in a soft state, otherwise it will pass through the intestinal canal without being broken down by the digestive process.

In chronic eczema, where the skin is of a dark venous colour, inactive, and without much heat, the poultice will be too sedative to be continued for any time; and, therefore, as soon as it has soothed the cuticular irritation, and cleared the surface of scabs, it should be discontinued, and the morbid skin dredged with flour twice a day. This will soon become encrusted, support the vitality of the integument, exclude the air, and allow the surface to heal; so that when the crusts are detached and fall off, the cuticle will be found restored.

Case.—I was requested to see a lady of advanced age, who had been affected with chronic eczema for some time on both legs. The cuticular surface was of a dark venous colour, and discharged a watery fluid, which formed scabs. The ankles and dorsal parts of the feet were somewhat oedematous; but the system was undisturbed. It was decided to try the poultice above described, and continue the liquor potassæ, which had been before taken. The local treatment was found comfortable and soothing, and in about a fortnight removed the oedema. The cuticle, however, showed no disposition to heal, and the temperature of the surface became so lowered that it was deemed necessary to discontinue the poultice, to dredge the legs twice a day with flour, and to substitute the nitro-muriatic acid for the liquor potassæ. The flour agreed well, and soon formed crusts over the whole of the disease, which were not disturbed; and as they loosened and fell off the cuticle was found restored.

SCABIES. (ITCH.)

Itch is an eruption of a local character, said to be produced by the irritation of an animalcule called "*acarus scabiei*." The eruption is sometimes small and vesicular, and at others comparatively large and pustular. It is, in either case, contagious, and appears principally between the fingers and toes and in the flexures of the larger joints.

Nothing is more easy than to diagnose this disease; and yet it is remarkable, amongst the better classes, how long a time will often be suffered to elapse before the proper remedy is applied, simply from an obstinate scepticism on the part of the patient, who is naturally anxious to escape the odium of having caught such a disease, as well as the annoyance of using the remedy necessary for its removal. In order to avoid the unpopular smell of sulphur, many remedies have been recommended for the cure of scabies, such as the white hellebore root, the nitrate of potash, dilute sulphuric acid, &c.; but neither of these can be depended upon, and they almost always fail to *eradicate* the disease. Mercury will sometimes succeed; and formerly it was the custom for old nurses to undertake the cure by

encircling the loins with a flannel girdle, smeared with mercurial ointment, and this mode of application was used as a means of introducing this medicine into the system, by which the disease was got rid of without further trouble; yet not always, for it not unfrequently happened that severe salivation was produced, which was a far more serious malady than that which it cured. There is, indeed, another external application, in which I have reason to have some experience, and that is the common solution of the chloride of lime. This should be well applied to the eruption, wherever it may be found, twice a day, by dabbing it with a bunch of linen rag, made wet with the solution. But, beyond all controversy, sulphur is the remedy most to be depended upon for the cure of scabies. It should be applied externally and taken internally. The ointment (1) is to be well rubbed into the pustules every night and morning for five or six days, after which the skin is to be washed clean with soap and hot water.

1.—R. Sulphuris Sublimati, oz. iij.
Adipis, oz. iv.
Olei Lavendulæ, gtt. v.

Misce fiat unguentum bis quotidie diligenter in partes affectas fricandum.

This process will generally suffice for the cure; if not it must be repeated in the same manner. In the mean time a scruple of this preparation of sulphur should be taken twice a day (if the patient be an adult) in honey or any other thick vehicle for three weeks. I have found the sublimed sulphur quite as effectual as the roll, which is unpurified sulphur; and it has the advantage of being less offensive in point of smell.

The pustules of scabies, if long neglected, will occasionally coalesce, and occupy a considerable portion of the skin with an intolerably itching scab. This is liable to be mistaken for an eczematous or impetigenous crust; but an examination of the pustules in other parts of the body will distinguish it from eczema; and the absence of stinging pain and cutaneous cracks from impetigo. The effect of external applications will also help us; for scabies will in nowise be benefitted by those which are soothing and curative; and in such eruptions the application of sulphur will not be tolerated by them.

Case.—An elderly female consulted me for a pustular outbreak on one of the legs, which had run into a filthy scab, occupying a large portion of the skin between the knee and ankle, discharging a thin matter, and causing intolerable and incessant itching. Believing the disease to be of an eczematous character, I treated it accordingly; but nothing that was applied had the least effect in lessening the eruption or abating the itching, which deprived her of all sleep and greatly exhausted her strength. Considering that it may have been originated by scabies, I next ordered the application of the sulphur ointment (1) which at once discovered its real character, put a stop to the itching, and removed the disease.

LEPRA. (LEPROSY.)

Lepa has been divided by pathologists into three principal species—the albidæ, nigricans, and candida;

but all are probably derived from the same root, modified by circumstances—constitutional or climatic. Malignant lepra is rarely seen in these islands, at least such a form has never fallen under my observation. This species is called “candida” from its bright whiteness, and the denomination has a complete agreement with that emphatically given to it in several parts of the Old Testament, such as “leprous as snow”—“a leper as white as snow.” It appears that in former times the malignant species was considered to be contagious, and hence those severe clauses in the Mosaic law, which excluded an Israelite, afflicted with this degree of the disease, from mixing with society. Celsus thus describes it:—“Leuce habet quiddam simile alphi, sed magis albida est et altius descendit; in eaque albi pili sunt et lanugini similes * * * Leuce quem occupavit, non facile demittit.” According to the same authority a singular method was practised to diagnose as to whether the disease was curable or not. “Utrum autem aliquod horum sanabile est, an non sit, experimento facillè colligitur. Incidi enim cutis debet aut acu pungi: si sanguis exit, quod ferè fit in duobus remediis locus est; si humor albidus sanari non potest.”—*Iber v.*

The lepra more commonly met with in this country is of the alphoid kind. It is characterised by elevated patches of squamous matter and of a dull white colour. When situated upon the spaces between the larger articulations, they are of a distinct circular form, about the size of half-a-crown, with a slight reddish areola; but they most frequently form upon the knees and elbows, where they are less defined. Sometimes the leprous surfaces are more extensive, occupying a considerable portion of the skin either of the extremities or trunk, associated with circular patches of small sizes here and there on the intervening spaces.

Lepa is accompanied with considerable local irritation; but although it continues for a long time, does not produce any great amount of constitutional disturbance.

In its more common form, the disease gradually yields to the efficacy of medicine. The liquor potassæ in doses of from forty minims to one fluidrachm, taken thrice a day in dilute milk, and the external application of the oxide of zinc ointment will not fail to be successful. But it will not always yield to this mode of treatment. There are examples of the alphoid character, which will not in the slightest degree be benefitted by it; but which will succumb to the use of the arsenical solution, as in the following case:—

A married woman, of middle age, and of healthy aspect, was admitted into the Royal South Hants Infirmary for lepra alphoides, which had existed a long time. It was extensive and confluent on the posterior surface of both arms, and small circular patches were thickly scattered over other parts of the body. She menstruated regularly and sufficiently. She was occasionally affected with hysteria, and her hands were as cold as stone and almost dripping with sweat; but notwithstanding this her general health did not appear to be much impaired.

She was first placed under the alkaline treatment, with a supporting diet; and the leprous surfaces were smeared with the oxide of zinc ointment, and afterwards with an alkaline application. Being in nowise benefitted by these means, she was ordered to take various tonics consecutively, such as the iodide of potassium, the disulphate of quinine, the compound iron pill, &c.; but as all these alike failing to make the slightest impression upon the disease, five minims of the liquor arsenicalis were given her three times a day. In a few weeks it was manifest that the disease was gradually yielding to the therapeutic influence of the remedy; and by persisting with the same dose for some time longer the skin became free from any leprous appearance.

APHTHA. (THRUSH.)

Thrush more commonly occurs either in early infancy or towards the termination of organic diseases. In the former it yields to the simplest remedies; in the latter it is incurable and is the forerunner of death. The thrush, however, may and does occur at other times, unconnected with the infantile causes or organic lesions; and this is the case alluded to here, which generally takes place in advanced age.

The disease invades the mucous membrane of the mouth, fauces, and alimentary canal; and it consists of small superficial ulcers, covered by a white deposit, but in some cases it is of a darker colour. The eruption, if such it might be called, is usually distinct upon the anterior and lateral surface of the mouth, and confluent upon the palate and fauces. It is often preceded by great drowsiness, which is followed by a burning sensation down the oesophagus and in the stomach, soreness of the epigastrium under pressure, and painful and difficult deglutition. These symptoms are accompanied with asthenic feverishness, depression, and debility. Thrush, under these circumstances, unconnected with organic disease, is curable, and by the following treatment:—The mouth and fauces are to be well washed or mopped out three times a day with the lotion 1; the bowels, if there be no diarrhoea, are to be regulated by 2, and the strength supported by 3, and a generous diet.

The chloride of sodium or calcium in solution is most efficacious in removing aphthæ from the mouth and fauces, indeed the rapidity with which they are removed by it is quite remarkable. I have met with several of these cases, three of which occurred to men over 70 years of age. Two were of the higher, and one of the lower, class of society. They all did well. It will suffice to relate one of them.

Case.—A gentleman, aged 78, whose residence was on a high hill, in a very healthy locality near the New Forest, complained of sore-throat, and requested my attendance. Upon examining the mouth and fauces the mucous membrane was found aphthous. Upon the cheeks the aphthæ were distinct, on the posterior part of the palate confluent, and they were of a whitish colour. The deglutition was painful and difficult. A sense of heat was felt in the throat and down the oesophagus, and his aspect was extremely depressed and debilitated.

The gargle (1) was prescribed, with which the mouth and throat were to be well washed three or four times a day. The bowels were to be moved with a gentle aperient, and one grain of the disulphate of quinine, as in 3, was ordered every four hours, with animal jellies, and a liberal quantity of wine. On my second visit, the next day but one, all the aphthæ were clean gone, and he was so improved in his general health as to be past all further anxiety.

Should there be d'arrhœa, which is not an unfrequent association with thrush, showing that the membrane of the alimentary canal is involved, a few drops of the liquor opii sedativus may be added to each dose of the quinine mixture.

Southampton, February 3, 1852.

[To be continued]

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM

CASES

Reported under the Terms proposed by the Association.

BY SCRUTATOR.

Fracture of the Femur; Post-mortem Examination.

WILLIAM DAVIS, aged 75, admitted into the Queen's Hospital, Jan. 13th, under the care of Mr. Knowles. He had, some short time before, slipped from a step and hurt his hip. On examination, the leg was found shortened almost two inches, the toes and knee turned outwards, and the hip much swollen. Upon making extension and rotating the limb, crepitus was plainly felt, and the case was diagnosed as fracture external to the capsule. The patient was very thin, had been suffering some time from extreme debility and cough, and apparently had scarcely had a sufficiency of food. A pillow was placed under the whole length of the limb,

and another rolled up under the knee, while fomentations were applied to the hip, and good beef-tea and arrowroot ordered for diet. The next day, however, the patient appeared sinking; the extremities were cold and the pulse feeble. Brandy and ammonia were ordered; but in spite of this treatment he gradually sunk, and died the third day after the occurrence of the accident.

On a *post-mortem* examination the day after death there was found to be an immense amount of effusion, not only beneath the integument, but also in all the structures between that part and the joint. The material effused was of a grumous nature, partly consisting of blood and partly of serum. The fracture was found to pass from the trochanteric fossa downwards and inwards, detaching the head and small trochanter from the remainder of the bone.

The joint laid open.

a Head of the femur.

b Line of fracture.

There are numerous interesting points connected with fracture of the neck of the thigh bone, and it is generally considered as divisible into internal and external, as regards the capsular ligament of the joint. Fracture within and fracture without the capsule do not very materially differ in their prominent signs, although there must of necessity always be a greater amount of shortening present when the solution of continuity happens externally to the capsule. Some observers have, however, stated that shortening is greatest in the internal fracture; but *post-mortem* evidence has not been brought forward to bear out the assertion. In some cases the extent of retraction will depend upon whether the capsular ligament is much torn.

Another point well worthy of notice in the case related is the manner in which the accident occurred. Fracture external to the capsule is generally occasioned by great and direct violence, while the other variety results from slighter and indirect degrees of force. That this, however, is not always the case the history of the accident given will sufficiently show, as the

fracture, although extensive, was produced by a slip from a low step.

With regard to the treatment of fractured neck of the femur, the general opinion is, that if the accident involve the internal portion no ossific union will occur, chiefly from the deficiency of a true periosteum. "Nature's object," says Sir Astley Cooper, "is to produce a ligamentous union, as best calculated for future motion; and the surgeon who is ignorant of Nature's object tries to effect an ossific union." A knowledge, therefore, of such facts is of the utmost practical importance, bearing as it does on the treatment to be adopted. A short time in bed, with support to the general health, will be all that is required, splinting and bandaging being dispensed with to the advantage of the aged. Should the fracture occur external to the capsule a different treatment may be employed. The double incline is perhaps as good as any position, and would probably have been used in the case related if the patient had survived the accident until it was judged necessary to employ retentive means. Such was Dupuytren's practice. Others use Desault's long splint, or one of the numerous modifications of that original. Sir Astley Cooper generally used the inclined plane, which also is recommended by Samuel Cooper, Ferguson, and others.

Encephaloid Tumour: Amputation.

DAVID LISTON, aged 28, admitted August 28th, under the care of Mr. Knowles. This man stated that five years back a small tumour appeared on the inner side of the right elbow, and that since it had gradually gone on increasing, and spreading over the front of the joint. He had never had much pain till lately, and worked at his trade as a silversmith up till four months back.

On examination there was a tumour, as large as a child's head, occupying the front of the elbow-joint, and extending half way up the arm, and nearly the same distance down the fore-arm. There was, however, some degree of motion in the joint, although the bulk of the abnormal growth prohibited its action. There were numerous blue veins on the surface; likewise elasticity to the touch. No enlargement of the axillary glands. There never had been any bleeding. He imagined it proceeded from a strain. General health, before tolerable, had failed of late, the tumour paining him much at night, and preventing sleep. Appetite bad.

October 4th.—The limb was this morning amputated about three inches below the head of the humerus, an internal and external flap being formed. There was a good deal of bleeding from the circumflex and profunda superior arteries, and as many as six ligatures were required. A ligature was also made use of to keep the flap together, and a roll of wet lint applied. This constituted all the first dressings. He made a speedy recovery, the ligatures all coming away by the 28th, and was discharged well December 7th.

On examination of the tumour it was found to present much the same appearance as brain, with here and there a large clot of black blood. The median and

ulnar nerves passed through its substance, as did also the ulnar artery, and the upper part of the muscles of the fore-arm were so infiltrated with diseased texture as almost to appear part of the tumour; below the mass they were sound. The anterior surfaces of the ulna and radius were denuded of periosteum for a small space, about two inches below the elbow-joint, but the joint itself was perfectly free from disease.

Amongst the points of interest connected with this case is undoubtedly the site of origin of the tumour.

It is still a disputed point, and cases have lately been brought forward where tumours of this description seemed to have their origin among the muscular structure; here, however, from the state of the parts, the morbid growth commenced from the periosteum. It has been stated that the periosteum is the only place of origin; but the fact that encephaloid tumours occur in the breast and other places, where there is no periosteum, sufficiently refutes this opinion.

Diffuse Cellular Inflammation; Amputation; Recovery.

JOSEPH PERKS, aged 14, admitted June 6th, under Mr. Parker. Nearly three weeks back what was described as a small boil appeared near the instep. The leg then became red, swollen, and very painful. A few days afterwards another boil appeared just below the knee. The first boil then burst, and a quantity of matter was discharged, after which the pain and swelling got better. The upper abscess then also broke. He does not remember receiving any blow or hurt. Such was the history of the case as given by his mother, who also added that he had been seen by a surgeon in the country, and that by his direction poultices had been applied to the limb.

On examination the leg was found free from inflam-

mation, and a small opening existed near the inner maleolus, which, on pressure above, discharged a thin material with shreds of flaky tissue. The integument as far as the knee was undermined on the whole of the anterior part of the leg, and a probe, if sufficiently long, might have been passed from the lower opening to the upper one beneath the integument. There was also several collections of matter at the posterior part, and diseased bone could be felt at several points. The pulse counted 130 in the minute, and was small. Great restlessness, urine loaded with lithates, and great failure of all the powers. As it was evident nothing could be done to save the limb, and as it was equally certain that death would be the result of the attempt, amputation was agreed upon; but as the lad was much exhausted by the exertion of travelling some miles to

the hospital, the operation was deferred for a day or two.

June 8th.—Mr. Parker amputated this morning above the knee, making two lateral flaps. Three ligatures were required and the patient was removed in a very satisfactory state. The stump was dressed in the course of the morning and he had some sleep during the day, and passed a very comfortable night.

9th.—Going on well. To have beef-tea.

22nd.—He went on well up to this date, when he complained of sudden pain in the right shoulder, which appeared somewhat fuller than natural. There was great pain on motion, and the stump did not present the same healthy appearance it had hitherto done, the discharge being small in quantity and of a sanious character. There was also diarrhoea and the pulse counted upwards of 100. He was ordered eight grains of Dover's powder, with five of aromatic confection immediately, six leeches were applied to the shoulder, and afterwards a blister. After this he got better, the pain and swelling left the shoulder and the stump slowly healed, but the last ligature did not come away until August 12th. He was discharged August 26th, the general health being quite restored.

Sympathetic and hectic fever are the general consequences of severe local disease, and although the system may not have sufficient power to establish a reparative action, yet it will always sympathize to the end with local affection. The cure, therefore, of this state can only be effected by the cure of the local disease, and if this is not practicable by its removal, the knife being called to our aid, supposing the case to be of such a nature as admits of operation. The immediate change for the better, after amputation, in persons who have been suffering from affections similar to the case related is very remarkable, all the constitutional irritation ceasing and the patient progressing, regaining health and strength. Professor Miller observes:—"It is better that a part of the body be destroyed, than that the existence of the whole be perilled; and diffuse inflammation of the cellular tissue sometimes, in spite of treatment, so far destroys the part as to render it necessary to remove it altogether. The amendment noticed immediately after the operation in this case was very great; his recovery, however, was for some time doubtful. Nature was left to herself, active interference being considered prejudicial, and no opiate or other medicines were exhibited.

Cancerous Disease of the Lower Jaw; Removal of Portions of the Bone.

JOHN ASHFIELD, aged 60, was admitted into the Queen's Hospital, November 16th, under the care of Mr. Parker, with an affection of a cancerous nature, involving the alveolar process and posterior part of the horizontal ramus of the lower jaw. There was no glandular enlargement present; but on examining the interior of the mouth a swelling, ulcerated in several places and very hard, was seen in the situation stated. The molar teeth had been lost; and he stated the dis-

ease had originated some four months before, his attention having been first drawn to it by the swelling which he felt. The disease did not involve the whole of the ramus, but reached apparently to its middle, leaving the lower portion free from disease. He wished to have the disease eradicated, and was willing to submit to any necessary operation. The general health was good, but the countenance somewhat pale. He was of a thin spare habit.

November 19th.—Some preparatory opening medicine having been previously administered, the operation was performed to-day by Mr. Parker, in the following manner:—An incision was first made of a semilunar shape, commencing near the lower border of the malar bone, and terminating near the symphysis of the lower jaw. The flap of integument was then reflected upwards, the cavity of the mouth opened, and the diseased part exposed, the facial and another small artery at this time requiring ligature. A small saw was next applied near the internal angle, and again at the anterior portion of the diseased part between it and the symphysis. The detachment was then completed by a pair of strong forceps fitted for the occasion, and the diseased mass removed, leaving a ledge of bone, consisting of the lower part of the horizontal ramus. After bleeding had ceased the parts were brought together by means of hare-lip pins, the patient put to bed, and wet lint applied over the wound.

20th.—Going on well.

22nd.—Some discharge from the points where the pins were inserted; the wound was elsewhere united. The pins to be removed. The internal parts are granulating, and look very healthy.

He continued to go on well, and was discharged December 6th, the general health being good, and the wounds, internally and externally, quite healed.

The necessity for removing the lower jaw, or a portion of that bone, can never arise except from some cause where life will obviously be endangered by not having recourse to the operation; and, although a formidable one to attempt, yet it then becomes the duty of the surgeon to face the difficulties which the urgency of the case requires. The disease for which the lower jaw is generally removed is tumour of a fibrous nature attached to that part; but it is sometimes necessary when the disease, as in the case reported, assumes a cancerous nature; and in such a case the sooner an operation is submitted to the more probability will there be of a favourable termination. Of course, if the glands surrounding the jaw should be indurated, or show any sign of cancerous degeneration, the operation, under such circumstances, will not present a prospect of benefitting the patient. The case related was very favourable as regards these points; and it is hoped no return of the disease will take place. He is now watched with great interest by Mr. Parker and others connected with the establishment. There are numerous methods by which the operation of removal of the lower jaw may be performed, most surgeons advocating their peculiar manner, as shown

by the writings of Dupuytren, Liston, Cooper, Miller, and others. But the direction of the incision for one case will not probably be applicable to another; and much, therefore, of necessity, must be left to the judgment of the surgeon who undertakes the operation.

Cancer of Penis; Amputation; Secondary Hemorrhage; Return of Disease.

SAMUEL HAYES, aged 49. This man had been under treatment some time for a scirrhus condition of the glans penis. He had applied to several practitioners and used many applications, but without obtaining any relief. When admitted into the hospital, he was advised to submit to amputation, but was unwilling to do so at that time; he therefore remained in the house some weeks until he became convinced of the necessity that some energetic measure should be adopted, and agreed that the operation of amputation of the penis should be performed. The history he gave of the complaint was, that three months before admission, the extremity of the organ was hurt by a stone, that a small sore appeared on the glans, which continued to enlarge, and ultimately implicated the whole glans and prepuce.

April 19th.—At the present time, the whole extremity of the organ seems converted into a hardened lobulated mass, with here and there slight abrasions, and in one or two places rather deep ulcerations. The general health is good and he does not appear to have been affected with phymosis. He never has had syphilis. There is very little enlargement of the inguinal glands; and upon the whole it seems a case very likely to terminate favourably, after recourse to the knife.

Mr. Knowles this morning (April 19th) removed the diseased part by one cut, the man having been previously put under chloroform. Two arteries were ligatured, and the man put to bed, with a piece of wet lint round the part; but in the course of an hour hæmorrhage came on to some extent, apparently of a partly venous and partly arterial character. The house-surgeon, Mr. Moore, then attempted to secure the bleeding vessels, but was not able to accomplish that object, from the great contraction of the corpora cavernosa which took place. Pressure, kept up for a considerable time, and cold having failed, Mr. Moore passed a catheter into the bladder, and having padded two small finger splints, placed one on the dorsum and the other on the anterior part of the stump, and then secured the adjacent ends of the splint with sticking plaster. This effectually controlled the hæmorrhage, and the man was at the same time able to empty the bladder, which since the operation had become very irritable, the patient continually wanting to make water, and disturbing the parts in the attempt. This apparatus remained on till night, when, to relieve the strain necessarily produced on the parts, the plaster on each side was cut, and the catheter retained till the morning.

20th.—Appears very comfortable; has no pain; pulse does not exceed 90. Catheter removed, and penis enveloped in wet lint.

21st.—Has made water well, and the stump appears beginning to granulate. To be dressed with simple cerate.

22nd.—Going on well. A cannula was passed into the orifice of the urethra which appeared contracted.

27th.—Both the ligatures came away to-day. He makes water tolerably, but the orifice appears much disposed to contract. To have a cannula passed daily.

29th.—Going on well.

May 2nd.—The wound is now well, but from the contraction which has taken place, the orifice of the urethra is almost hidden by the integument, and the orifice itself is contracted much, requiring the daily passage of an instrument. He remained improving, and in some few days the question of his discharge was mooted, when a suspicious-looking pimple appeared (first noticed May 20th) on the integument of the penis, of a dark colour, and hard to the touch. This was in a day or two followed by another, and this again by a third, the inguinal glands, at the same time, beginning to enlarge and grow painful; the testicles also became swollen and tender, and the cannula was again requisite to afford a free exit for the urine. He remained in the hospital during the month of June, on the 23rd of which an incision was made into the swelling at the groin, from which issued pus, grumous blood, and concrete particles of a chalky character. He continually suffered great pain, but was relieved to some extent by morphia, being at the same time supported by stimulants and good diet. During the month of July the disease in the right inguinal region increased, and presented the melancholy spectacle of an open cancerous ulceration. He now began to have attacks of hæmorrhage, which on one or two occasions were checked with difficulty; but his health, strength, and spirits kept up in a remarkable manner. He eventually left the hospital in August, but did not live long after his departure.

Cancer of the penis is always of the scirrhus variety, never of the encephaloid; although when the inguinal glands become affected, the disease in that part may approach near to the encephaloid character. In general it commences as a small warty excrescence, or sometimes as a small pimple, first making its appearance on the glans penis. It sometimes is traceable to a blow or other injury, as in the case reported; but frequently no exciting cause is obvious. Cancer, however, according to the best authorities, may begin as a general thickening of the whole prepuce; and in this case a small ulcer at last forms, which may be mistaken by the inexperienced for a chancre, or syphilitic sore. The history, however, of the case, coupled with the fact that remedies have no power over the cancerous ulceration, would sufficiently point out the diagnosis. Warty growths, from their liability to degenerate, should always be looked upon with suspicion; as, although not essentially cancerous in their origin, they may become so, aided by dirt and stimulating applications.

Cancer of the penis is a disease of advanced life, and it is frequently found coupled with a natural or acquired phimosis, which fact was noticed years back by the late Mr. Hey.* Jews are said to be free from this disease, which, if a fact, must be explained by the operation they undergo. As regards treatment, surgical authorities are pretty well agreed that amputation should be performed as early as possible, that is to say, as soon as there is no doubt felt concerning the nature of the affection. This was the opinion of Fravers, Hey, Cooper, Liston, &c., but is designated by Dr. Walshe as a "peculiarly sorry" resource. If there be no swelling of the inguinal glands, and the general health is good, there can be no doubt of the propriety of the operation, especially as when the penis is affected, one objection raised against interfering with malignant growths is done away with, viz., "that no operation by excision is performed without the chance of leaving some of the diseased structure behind." If the disease is confined to the penis, it can certainly be removed. Should, however, the inguinal glands be affected, the operation should not be attempted, and it sometimes is a difficult thing to decide between a sympathetic enlargement, and the commencement of scirrhus.

As regards the manner in which the operation of amputation of the penis should be performed, the rule of saving as much as possible of the organ should always be followed, but the plan of drawing the integument towards the pubes, before the incision is made, sometimes recommended, is not necessary, as the corpora cavernosa always retract so much as to leave a sufficiency of skin, and in many cases a redundancy. It seems of more importance to draw the integument away from the pubes, as by not leaving much we obviate the propensity to contract, which the orifice of the urethra so frequently shows.

Another prominent reason why too much skin should not be saved is, that the arteries cannot be secured, if covered to such an extent, as they frequently are, from the contraction of the corpora cavernosa. The hæmorrhage after this operation is frequently profuse, and often with difficulty restrained, and it therefore becomes a matter of importance to perform the operation in such a manner as will allow of that object being easily attained. In the case related the contraction was such that the bleeding vessels could not possibly be secured,† and it was not until the patient was reduced to a very weak state that Mr. Moore hit on the plan which was so successfully carried out. Styptics, circular pressure, and the actual cautery, have all been used in cases of hæmorrhage from this part, but should another case occur to the writer, he would decidedly practise the plan pursued by Mr. Moore; it not only restrains the hæmorrhage, but at the same time keeps the urinal passage free.

On examination of a thin portion of the amputated part the characteristic appearances of cancer were

recognised, the cut introduced being a copy of the field taken from a drawing made at the time.

Without any addition

After the addition of acetic acid.

Provincial Medical & Surgical Journal.

WEDNESDAY, MARCH 17, 1852.

IN consequence of the recent Ministerial changes, the deputation which was to have waited upon Sir GEORGE GREY, on the 26th ultimo, received an intimation from that gentleman that he would be unable to forward their views by an interview as previously promised. This unfortunate *contretemps* has so much impeded the progress of "The Bill," that we are at present unable to afford much ground for hope of proceeding with the measure during the present session.

It may appear to a casual observer that the mere substitution of Mr. WALPOLE for Sir GEORGE GREY, can be of no great consequence to the success of a bill for regulating the medical profession; but we can assure our readers that the removal from office of the latter gentleman, has rendered it necessary to begin *de novo* so far as Parliament is concerned. For not only must we gain access to the present Secretary, or to some other leading Member of the House of Commons, but it is also requisite that the person who undertakes to settle this abstruse question should

* Hey's Practical Observations.

† For cases of this kind see Hey's Practical Observations, Cooper's First Lines, and Eoder's Journal.

study the subject in all its bearings, so as to know what are really the claims and grievances of the various parties who come to him with statements as varied as the points of the compass. Now this had been carefully done by Sir G. GREY, who had, in conjunction with the Lord Advocate, given so much attention to the subject as to understand it as well as if really one of ourselves; and it is true that we might have endeavoured to persuade him to introduce the Bill as a private Member of the House, but then the expense would have fallen (and we are sorry to say the sum is no light one) upon the promoters of the Bill, who have no funds at command to meet such a heavy expenditure. Under these discouraging circumstances the Worcester Council have endeavoured to open a negotiation, of which we hope to announce the success in a future number of the *Journal*.

There are, however, two or three points for consideration, which may, if conceded, materially diminish the opposition to the Bill, whenever it is introduced into the House of Commons. It is proposed, by a very influential party in the profession, that it shall be provided that, after the student shall have passed all the examinations appointed by the General Licensing Board, *and before receiving his licence*, he shall obtain the diploma either of the College of Physicians or that of the College of Surgeons. So that, in future, every medical practitioner in England and Wales shall, as in Scotland, be either a physician or surgeon, and be attached to one or other of these Colleges. Now, if these Colleges were in a satisfactory state as regards their internal management, and really represented the interests of their respective portions of the profession, we should think the alteration a great improvement; but, unfortunately, the recently-granted Charter of the College of Surgeons, by its provisions, effectually repudiates the whole of the provincial surgeons as electors to the Council, and consequently only represents that portion of the profession resident in London and its suburbs. Against this unfair and exclusive clause we have over and over again protested, and we cannot, therefore, quite understand the propriety of aiding, by such means, in increasing the powers of the College, whilst we in the provinces are studiously excluded from our legitimate right to a share in the management and control of them. We can easily imagine that the London Colleges would gladly support

the Bill with such a provision, since it would increase the funds of the College of Physicians twenty-fold, and add, at all events, one-third to the coffers, already overflowing, of the College of Surgeons.

Our anxiety to settle this all-important question is so great, that we would gladly concede any matter of ordinary importance, if by such concession we could ensure that success which is so much coveted by all well-wishers to the measure; but we cannot consent to cut our own throats, nor can we, unless the obnoxious restriction is removed, (it was only carried by a very slight majority in the Council Chamber,) consent to increase the powers of so unreasonable a body. It is far better to put off the day of settlement, than to settle in such an unsatisfactory manner a question which could not be reopened for many years to come.

WE are authorised to state that the Anniversary Meeting of the Association will take place this year at Oxford, on the 21st and 22nd of July. The appointment is made rather earlier than usual, in consequence of an intimation from the authorities to the effect that it would be more convenient to the University to have the meeting held before the end of July.

Reviews.

The Fallacies of Homœopathy and the Imperfect Statistical Inquiries on which the Results of the Practice are estimated. By C. H. ROUTH, M.D., M.R.C.S., &c. London: Lewis. pp. 85.

To every adult mind unwarped by self interest, and unimposed upon by the wayward manifestations of what the phrenologists would call the "organ of marvellousness," the doctrines of homœopathy must appear so utterly baseless, tested even by common sense, that a set refutation of their hollowness will appear uncalled for. Unfortunately, however, there is among the public so much unreflecting credulity on medical subjects, and, with shame be it said, among some members of the profession, so plain a tendency to make a profit of that credulity, that it has become a matter of duty as well as necessity to exhibit the delusions of this miscalled science, in the clearest possible light. Several worthy attempts have from time to time been

made to effect this laudable object, but it has not occurred to us to meet with any refutation of the Hahnemannian theories more complete and crushing than is contained in Dr. Routh's pamphlet. We would not value at much either the intellect or the honesty of any man who can remain a homœopathist after perusing its pages.

The Medical Directory for 1852. London: Churchill.

WE have hitherto spoken of this work in terms of commendation, as we believed it to be calculated to be of great service, both to the profession and the public. It is with regret, therefore, that we see apparently a fixed determination on the part of the Editors to include a register of all and sundry quackeries, simply because those professing them happen to possess legal qualifications. This is, in our opinion, a great mistake, and one which, if not rectified in future editions, will seriously affect the *Directory* as a commercial speculation.

Proceedings of Societies.

SOUTH-EASTERN BRANCH.

NAMES of Members of the Provincial Medical and Surgical Association in the SOUTH-EASTERN DISTRICT, who have expressed opinions or wishes respecting the Medical Reform Bill, to the Secretary of that Branch, March 10th, 1852:—

F. H. Sankey, Esq., Wingham—Approves on the whole, with exceptions.

J. C. Prance, Esq., Maidstone—General view in favour of the bill.

Andrew Sisson, Esq., Reigate—Sincere approbation.

F. T. Giraud, Faversham—Approves in general terms.

Butler Lane, M.D., Ewell—The principles of the bill approved.

S. S. Stedman, Esq., Arundel—Favourable.

George Moore, M.D., Tunbridge Wells—Quite approves.

George S. Sloman, Esq., Farnham—Much approves.

James Reid, Esq., Canterbury—Supports and approves with qualifications.

N. Tyache, M.D., Chichester—Qualified approbation.

W. S. Hoare, Esq., Faversham—Approves.

John Adamson, Esq., Rye—Declines an opinion.

George Rigden, Esq., Canterbury—General approbation.

Edward Wallace, Esq., Carshalton Disapproves of the bill

Frederick Sopwith, Esq., Ightham—Approves with modifications.

John Hackway, Esq., Boreham—Entirely approves.

James Dickson, Esq., Brighton—Approves with one exception.

C. M. Thompson, Esq., Westerham—Unfavourable opinion.

John Beet, Esq., Ashford—Approves with exceptions.

William Harris, Esq., Worthing—Perfectly accords.

John J. Terry, Esq., Wittersham—Approves in some degree.

Wm. Wallis, Esq., Hartfield—Qualified approbation.

William Davies, Esq., York Town—Thinks well of the bill.

G. Soulby, M.D., Dover—Approves with exceptions.

R. N. Trew, Esq., Steyning—Approves with one or two exceptions.

Henry Collet, Esq., Worthing—Has no objection.

Henry Prout, Esq., Yalding—Approves.

Richard Turner, Esq., Tunbridge Wells—Approves.

Geo. S. Jenks, M.D., Brighton—Approves with modifications.

Robert Ranking, M.D., Hastings—Thinks it calculated to be an useful measure.

DORSETSHIRE BRANCH.

A MEETING of the members of the Dorset Branch of the Provincial Medical and Surgical Association was held on Tuesday, March 2nd, 1852, at the County Hospital, Dorchester, to consider the proposed "Medical Reform Bill."

Dr. COWDELL, President, in the chair.

Proposed by J. S. DANIELL, Esq., of Blandford, seconded by A. EMSON, Esq., of Dorchester, and carried unanimously,—

"That this meeting fully concurs in the opinion that the laws regulating the profession of physic and surgery require to be amended, but feels strongly that the Apothecaries' Company has acted in such a manner as to deserve the entire confidence of the profession, and by its regulations continually tended to raise the standard of medical education higher and higher, and now only needs increased powers to meet every requirement for the duly examining and qualifying for medical practice, and the effectual protection of medical practitioners when qualified."

Proposed by Dr. ALLEN, of Bridport, seconded by JOHN WALLIS, Esq., of Dorchester, and carried unanimously,—

"That, in order to define more clearly the body of legally-qualified medical practitioners, and to enable the public to discriminate between these and persons fraudulently assuming medical titles, it is desirable to provide, that all persons possessed of legally-recognized diplomas, or licensed to practise medicine in any of its branches, be compelled to exhibit and register the same; that the date of each diploma thus presented, the title of the body comprising it, and the name and residence of the recipient of it, be registered; that annual certificates be issued to registered persons, and an alphabetical list of such registered practitioners be furnished to every person receiving a certificate, such

list to specify the nature and qualification of each medical practitioner; this register to be published one month after the last day appointed for registration, and to be received as legal evidence in the absence of positive proof to the contrary, of the qualification of any medical practitioner."

The meeting also discussed the proposed New Charter of the College of Surgeons, and it was

Proposed by GEORGE CURME, Esq., of Dorchester, seconded by F. G. GOLDSMITH, Esq., Dorchester, and carried,—

"That this meeting considers it incumbent on the Council of the Parent Association to protect the interests of the provincial surgeons, and to represent strongly the injustice which would be perpetrated on them if, in the New Charter, sought for by the Royal College of Surgeons, the election of fellows should be carried by the votes of those who may be enabled to attend personally, which would, in fact, render the privilege of voting a boon in words, but not in reality, to the provincial surgeons."

CHARLES COWDELL, M.B., &c.,

President of the Association.

HENRY ALBAN ARDEN,

Local Secretary.

SUFFOLK BRANCH

A MEETING was held at Stowmarket on the 24th ultimo, to consider the proposed Medical Reform Bill. As the members present consisted only of the President, the President-elect, the Secretary, and the Ex-Secretary, no measure of a representative character could be proposed. Letters expressive of regret for non-attendance were received from Dr. Durrant, Mr. Bullen, Mr. Growse, Dr. Growse, Mr. Robt. Growse, Mr. Gorham, Dr. Wake, and Mr. Williams; and after the suggestion of a request that the members would communicate their views, either for or against the proposed Bill, to the Editors of the *Provincial Medical and Surgical Journal*, the meeting separated.

JOHN KIRKMAN, M.D., Secretary.

ROCHDALE MEDICO-ETHICAL ASSOCIATION.

To J. P. Sheppard, Esq., Secretary to the Council of the *Provincial Medical and Surgical Association*.

SIR,—I am directed to forward you the following resolution unanimously agreed to at a meeting of the Rochdale Medico-Ethical Association, held on the 22nd March:—

"That this Society having taken into consideration the Draft Bill prepared by the Provincial Medical and Surgical Association, expresses its approval of the same. That the Secretary be empowered to communicate with the Provincial Association to this effect."

I remain, Sir, your obedient Servant,

J. E. WOOD, Hon. Secretary.

Rochdale, March 4, 1852.

PATHOLOGICAL SOCIETY OF LONDON.

DR. LATHAM, PRESIDENT, IN THE CHAIR.

Cholesteatomatous and Cystic Tumour of the Ovary.

By MR. ADAMS.

The parts were removed from the same case as the specimen of necrosis of the head of the femur, exhibited by Mr. Solly. The tumour occupied the situation of the left ovary, and had a coarsely lobulated outline, the average diameter being about three inches, or rather more. On section, it resembled, in its anatomical arrangements, the ordinary compound cystic tumour of the ovary, when of small size, the cysts, however, containing a very different material to that usually met with. There was a slight peculiarity in the cysts, viz., that they appeared less compound than usual; they were more independent of each other, so as to suggest the idea of their being a cluster of solitary cysts, rather than a group originating by multiplication from a single cyst; from the internal surface of one of them, however, a flattened cluster of compound secondary cysts projected into the cavity of the parent cyst, precisely as in the ordinary compound cystic tumour, so that no difference in respect of their origin and development could be presumed. The contents of the cysts formed the only peculiarity. There were four principal cysts; one occupied the precise position of the ovary, with thick, dense parietes, and filled with a firm, waxy-looking material, loosely contained in the cyst, from which it easily shelled out entire. The surface of this waxy-looking substance had a brilliant mother-of-pearl appearance, and was smooth and even, with the exception of a few small granular elevations. A section through this spherical mass exhibited the following appearances:—The central part was of a dingy brown colour, and of cheesy consistence, homogeneous, and without a laminated arrangement; this colour ceased rather abruptly at two lines from the surface, the peripheral portion for a line in thickness, having a dead white pearly appearance; this part had also a distinctly laminated arrangement of structure, the laminæ being extremely thin, but separable readily by the point of the scalpel. The laminated arrangement, though most distinct at the circumferential portion was not confined to it, but extended through the dark-coloured part towards the centre, gradually getting less distinctly traceable as it approached this point, where it was completely lost.

On a microscopical examination, the circumferential part was seen to consist of laminæ, having very much the appearance of tessellated epithelial cell-membranes, intermixed with layers of cholesterine crystals; the cells were irregular in form, generally hexagonal or polyhedral, very transparent, with a pale, delicate outline, and always without nuclei or granular contents, resembling scales therefore, rather than cells; although they generally presented themselves in membrane-like masses, individual cells readily separated and presented the characters above described. The crystals were extremely abundant at and towards the circumference,

but diminished rapidly towards the centre, where they were absent. The cells, too, gradually lost their scale-like character, became more regularly spherical, and contained oil as they approached the centre; they still generally presented themselves in membrane-like masses, but individual cells separated much more readily. The surface of the separated cells frequently had a wrinkled appearance, probably from the escape of a portion of the contained oil. A second cyst of oblong form measuring an inch and a half in its long diameter, passed directly outwards, one of its small extremities being adapted to the convex outline of the spherical cyst above described; it had thick parietes externally, and a thin membranous wall on its central aspect, and contained cholesteatomatous matter resembling in its microscopic characters that above described, but of a whitish, translucent, waxy, or spermaceti-like appearance throughout, and less regularly disposed. The dense, laminated material of mother-of-pearl lustre, above described as surrounding the spherical mass, existed here only at the small end in apposition with the spherical cyst, and along the sides to a variable extent. A third cyst of spherical form, nearly two inches in diameter, and situated laterally with respect to the two last-described cysts, was filled with a clear and slightly viscid or gelatinous fluid, such as is constantly met with in ovarian cysts; examined microscopically, this fluid was seen to contain masses of a finely granular matter mixed with spherical cells like mucous corpuscles; no crystals were seen, but only a small quantity of this fluid was examined, most of it having escaped on opening the tumour; however, the fluid contents of some of the smaller cysts, from the cluster of compound cysts, was carefully examined, and presented similar appearances. The cluster of compound cysts alluded to was in apposition with this cyst, and also with a smaller one to be next described, between which it was compressed. The small cyst adverted to was of a narrow, oval form, less than an inch in its long diameter, more central in situation, and having thin membranous parietes; it was filled with a white granular fatty substance of very soft consistence, resembling that met with in the ovarian cysts which contain hair, &c. Under the microscope this substance was seen to consist of cells filled with oil; the cells were of the same size and appearance as those described in the central part of the spherical cholesteatomatous mass from the first cyst, but completely spherical, being distended with oil, and without any tendency to cohere; cells having a slightly wrinkled appearance from the partial escape of oil were also numerous. A portion of this fatty substance was allowed to remain a few hours on a piece of writing paper, on which it left a large greasy spot.

These appearances seemed to favour a suggestion made by Dr. Bristowe, that the cells or scales intermixed in membranous layers with the crystals of cholesterine, principally on the outer portion of the cholesteatomatous masses were identical with the oil-containing cells in the central portion, and the fatty substance in the fourth-described cyst being derived from them by the simple exudation of their oily contents,

instead of being formed by the shedding of epithelium in successive layers from the walls of the cysts into their cavities as described by Müller. The crystals seemed to abound in direct proportion to the disappearance of the oil from the cells, and therefore existed in greatest abundance at and towards the surface of the cholesteatomatous masses.

Hydatid Abscess of the Liver, opening into the Right Pleural Cavity.—By DR. BRISTOWE.

W. W., a chairmaker, aged 20, was examined the 24th November, at 1 P.M., having died at 2 A.M. the same morning. For three years he had been ailing. A month before his death he is said to have had a very severe attack of fever, accompanied by intense pain in the right side, and at this time enlargement in that neighbourhood was first noticed. It is most probable that the attack of fever marked the occurrence of suppuration of the hydatid cyst. The fever diminished, but the pain and swelling of the side continued or rather increased, up to the time of death.

At the *post-mortem* examination he was found extremely emaciated. The right side of the chest and abdomen was very prominent and bulging; the parietes tense and smooth; large veins were seen running superficially over the right hypochondriac region and lower part of the chest, and numerous hæmorrhagic spots were scattered over this part. At almost the first incision through the cartilages of the right ribs, a small amount of somewhat offensive gas escaped, together with a quantity of thin, yellowish pus, in which were floating numerous hydatids; these were all collapsed or broken, and of a yellow colour, many containing large bubbles of air. On laying open the chest, the pleural cavity was found full of fluid similar to that which had escaped, its amount being several pints. The lung was collapsed, airless, and much reduced in size, covered by a layer of opaque, buff-coloured, somewhat soft fibrin, a portion of which glued the lobes of the lung to one another, and the base of the lung to the diaphragm. The parietal pleura was similarly covered. Immediately in front of the root of the lung, the fibrinous deposit was more abundant, and there was a small quantity of thick creamy pus, which, on applying pressure to the liver, was somewhat, but very slowly, increased in quantity. The liver was very large, extending from below the umbilicus to the space between the fourth and fifth ribs. The left lobe was somewhat larger than natural, but the great increase in bulk was due to enlargement of the right lobe, which seemed almost entirely converted into a large fluctuating cyst. The liver was adherent above to the diaphragm, but free elsewhere. On making a section through the anterior part of the cyst, a large quantity (four or five pints) of thick, white, creamy pus escaped, together with numerous hydatids, resembling those obtained from the pleura in every respect, except that of containing air. Among the hydatids was one imperfect, but of very large size, which had probably, previous to the occurrence of suppuration, formed the lining of the cyst; this was very adherent at one part, and, on removal, a portion of it was found crumpled

up, and deeply stained with bile. On washing out the cyst, its parietes were seen to be formed of a firm, whitish, fibrous material about a line in thickness, not laminated nor containing any earthy deposit, but presenting a somewhat reticulated surface, and in places aborescent markings, evidently the remains of obliterated vessels. At the upper part, where adherent to the diaphragm, the cyst-wall was thicker and firmer than elsewhere, and made up of condensed liver-structure and diaphragm inseparably united; this was partially destroyed in places by small, well-defined, sinuous ulcers, and was circumscribed also by ulceration, which had in many places laid bare the muscular fibres of the diaphragm; this was especially the case on the inner side, where they were exposed and perforated; the orifice, however, was in great measure plugged up by a considerable quantity of the lining of the cyst, which had been partially detached by ulceration. It was through this opening that the communication with the pleural cavity was established. At the posterior and lower part of the cyst was a somewhat valvular, oblique opening, large enough to admit the tip of the forefinger; it was found to be the orifice of the right hepatic duct, at about two inches from its junction with the left; the duct between these points was dilated and pale, contrasting remarkably with the left and common ducts, which were stained with bile; it was here beyond doubt that the large hydatid before mentioned had become fixed. This explains the adhesion that was noticed, the crumpled and bile-stained appearance of part of it, and also the paleness of the duct itself. On examining closely the parts in the neighbourhood of the orifice, it was seen that the posterior wall of the duct was prolonged in a branching form for some distance on the posterior wall of the cyst; that the prolongations were smooth and polished as the duct itself, distinctly margined, and presenting the orifices of other ducts, along some of which a probe could be passed for some distance. The walls of the cyst were about a quarter of an inch thick in front, and half that behind; they were made up externally of flattened liver structure, and internally of the proper fibrous cyst-wall: the two, however, were inseparable, and passed gradually one into the other. The former presented microscopically an increase of fibrous tissue, with an almost entire absence of liver cells, which were replaced by granules of oily material free and clustered; the latter presented almost the same characters, except that the granular material was in smaller, the fibrous in greater quantity. The microscopic characters of the left lobe were normal. The heart was very much pushed over to the left side, but that and all the other viscera were healthy. Besides the general interest of the above case, there are two or three minor points worthy of notice. 1st. The occurrence of air in the pleura—its presence in that situation, independently of pulmonary lesion, is very rare. In this case, though not noticed, it undoubtedly existed during life, and there is every reason to believe it was due to decomposition in the hydatids themselves, as the air was found not only free, but enclosed within them. 2nd. The contents of hydatid abscesses of the liver are

usually tinged with bile, whereas here they were almost a pure white, even though a large bile-duct opened directly into the cavity. It is certainly possible that the entrance of bile into the cyst was the primary cause of suppuration, and that the blocking up of the orifice by the hydatid prevented any further ingress of that fluid, and consequently enabled the contents to preserve their colour; but Dr. Bristowe was much more inclined to believe that in this case, and probably in many others, the suppuration was due to some other cause than extravasation of bile, and that the patulous state of the duct was a natural appearance resulting from the development of the hydatid within it. This is borne out by the facts, that there was no appearance of anything like ulceration in the neighbourhood of the orifice, that the duct opened abruptly into the cyst, instead of presenting a lateral ulcerated opening, and that its continuation on the wall of the cyst was smooth, polished, and with even margins; and it can scarcely be imagined that ulceration should have perfectly destroyed one half of its calibre, leaving the remainder in the healthy and perfect condition in which it was found.

Great Enlargement of the Head, occasioned by a Morbid Growth from the Cranial Bones.—By MR. STANLEY.

This occurred in a farmer's boy, aged 15, who had been repeatedly struck upon his head with the handle of a pitchfork. On one occasion the blow was so severe that it stunned him, and, about a month afterwards, he perceived a lump upon the top of his head, which gradually extended through the following two years over the whole of the superior, lateral, and posterior parts of the cranium. The form of the swelling was such, that being covered by the scalp stretched over it, the aspect was that of an additional cranium growing from the vault of the skull. The increase of the morbid growth was accompanied by severe pain in the head, also by great enlargement of the bloodvessels of the scalp, and by loss of sight, first in one eye, then in the other. At length sloughing and suppuration ensued in the scalp, as the consequence of its stretched and inflammatory condition, and after severe suffering for nearly three years, convulsions ensued, under which he sank. On examining the head, a morbid growth was found arising from the outer table of the cranium through the greater part of its extent, and a similar growth was found arising from the inner table, and thence extending into the cranial cavity, causing, by its pressure, absorption of part of the cerebral hemispheres. The cranial bones intervening between the morbid growths were found thickened and otherwise altered in texture. The morbid growth from the outer table of the skull was firm, and of a whitish colour; it had not the characters either of hard or soft cancer, nor was it fibrous. The morbid growth from the inner table was somewhat softer, and of a darker colour.

Dr. Jenner, who had undertaken to examine and report on the microscopical characters of the preceding specimen, detailed the appearances observed in different portions of the tissue, and concluded that they may be

grouped under four heads:—1st. The normal elements of the parts, more or less changed, *e. g.*, the nerve cells. 2nd. Fibro-plastic corpuscles, fusiform fibres, and free nuclei. 3rd. White fibrous and yellow elastic tissues. These, perhaps, owed their origin chiefly to the development of the fibro-plastic corpuscles; probably, however, they were partly the remains of the elements of the normal tissues of the parts. 4th. The products of inflammation, *e. g.*, the non-nucleated granular corpuscles, and molecular protein granules. In different stages of development, in different states of decay or degeneration, and variously combined and arranged,—these constituted the portions of the growth which he (Dr. Jenner) had for examination. A question may be entertained, whether in this case the fibro-plastic element, and, consequently, so much of the fibrous tissue as had its origin in it, may not have been developed from a blastema, the product of inflammatory action; certainly, fibro-plastic corpuscles and fusiform fibres are sometimes found on serous membranes, as the result of the development or organisation of inflammatory exudation matter, and it would appear to depend, partly at least, on the constitutional state of the patient to determine whether inflammation shall cause the exudation of simple fibrillating contractile lymph, a blastema capable of evolution into fibro-plastic tissue, pus, or granular corpuscles, and protein molecular granules. But, whether themselves originating in inflammatory action or not, it is universally admitted, that fibro-plastic growths are, like all vascular structures, capable of becoming inflamed, and to the inflammation set up in the growth itself the softening and the granular corpuscles seem in this case to have been due. In the parts in which these corpuscles and granules were the most abundant, fat was found in the largest quantity. This fact lends support to the opinion, that this form of exudation undergoes fatty degeneration with greater facility than most other forms. With reference to the question of malignancy, the only conclusion warranted by the microscopical examination is, that it was locally, but not constitutionally, malignant; at the same time, it seemed to him that our acquaintance with the microscopical characters of morbid growths, the histories of which prove them unequivocally to have been constitutionally malignant, is not sufficiently extensive for a definite statement to be made on this point.

FRANCE.

On Pilimiction, or passing of Hairs with the Urine.

This is the title of a lengthy essay by M. Rayer, published in the *Gazette Medicale*. The author believes that the hairs occasionally observed to be passed with the urine, or engaged in calculi, may arise from three sources:—1st, original formation in the urinary passages; 2nd, evacuation from cysts; 3rd, introduction from without.

The first is a very rare occurrence; it is distinguished by the hairs being passed either in natural or bloody urine. They are passed without pain in many cases, but where there is a bloody or purulent urine, there is generally considerable suffering.

The evacuation of hair from cysts has usually been observed in women, and it is presumed that the discharge comes from ovarian tumours, which have burst into the cavity of the bladder.

Hairs may be introduced into the bladder in some of the semi-nymphomaniacal conditions observed in women; they are known to become the nucleus of calculi. Rayer thinks it not unlikely that hair and other matters may be introduced by the careless performance of lithotomy.

On Infantile Paralysis.

In an essay by M. Rilliet, (*Archives Générales*), on “Essential Paralysis of Infants,” we find a large amount of interesting matter, the most practical portion of which we shall endeavour to condense.

1. *Definition*.—The author applies the term “Essential Paralysis” to more or less complete loss of power, with or without loss of sensation, and unaccompanied by any signs of lesion of the nervous centres. This form of paralysis is often incurable, but does not of itself shorten life, for which reason it is difficult to find its structural causes; for even if the spinal marrow or brain shall exhibit certain lesions, it becomes doubtful whether they are not the results, rather than the causes, of the paralysis.

2. *Seat and Mode of Attack*.—Essential paralysis occurs in three different ways:—Sometimes it attacks the patient suddenly in its highest degree, and without obvious cause; at other times it is preceded by cerebral disturbance and convulsions, as during dentition, but in these cases, also, the loss of power is sudden, and not progressive. Thirdly, it may approach gradually.

When paralysis is sudden, and not preceded by cerebral symptoms, it mostly appears in the upper extremities. An infant goes to bed well, and next morning it is found paralyzed in one arm. Another sits on the damp ground, and one leg is suddenly discovered to have lost the power of motion. At the same time there is no perceptible derangement of the general health.

When cerebral symptoms precede, these usually consist of somnolence, strabismus, dilatation of the pupil, and headache. These symptoms speedily subside. At other times violent and repeated convulsions occur; these cease, and paralysis is found to have supervened. Paralysis sometimes succeeds chorea, as in the cases cited by Drs. Kennedy and Lee. It also appears in the course of exanthematic fevers, and is then generally discovered for the first time when convalescence commences.

3. *Symptoms and Progress*.—In whatever way infantile paralysis commences, it presents two periods,—one, that of paralysis, the other, that of atrophy. In some fortunate cases the disease does not proceed to the latter extent. The symptoms vary with the part affected. If the arm is the seat of the disease, it hangs

lifeless, and if lifted falls again to the side. The paralysis is sometimes complete, at other times limited to certain sets of muscles. In some instances the fingers are flexed upon the thumb.

So also in the lower extremity the loss of power may be complete, or partial. If the child does not walk, it kicks the sound leg about, while the other lies motionless. The paralyzed limb is not the seat of any pain. The colour and temperature of the skin are often normal. The sensation is generally intact. In fact the paralysis of motion constitutes the entire malady.

The progress of the disease is not always the same; it may disappear completely, and rapidly, or it may persist with or without amelioration. In the latter case, sooner or later, the second period or that of atrophy commences. This is marked by diminution of temperature, wasting of the muscles, and arrest of growth of all the structures together, so that the limb is perceptibly smaller and shorter than the other. In proportion as the temperature diminishes so does the skin change colour, becoming more and more livid.

Fresh observations on the condition of the vessels of paralyzed limbs are necessary, but it is obvious that these tubes are involved in the general atrophy. The pulse at the wrist is, in some cases, scarcely to be felt.

As a further consequence of infantile paralysis, the spinal column becomes variously distorted, and the limbs themselves may be deformed. Thus, in paralysis of the arm, and atrophy of the deltoid, the head of the humerus may be completely dislocated, the weight of the limb stretching the capsular ligament, until it allows the head of the bone to glide out of the glenoid cavity. Such cases are described by West, and one is reported by the author of the present memoir.

Heine has described deformity of the lower limbs thus paralyzed, consisting of flexion of the thigh upon the pelvis, and of the leg upon the thigh. The paralysis of one set of muscles, and antagonistic contraction of others, gives rise to the different varieties of club-foot.

4. *Prognosis*.—Essential paralysis does not compromise life, but as it in some cases disappears rapidly and completely, while in others it is perfectly incurable, it becomes important to determine the circumstances which should lead to a favourable or an unfavourable prognosis. This, according to Kennedy, is to be known by the manner in which the paralysis has occurred. The author of the present memoir does not agree in this opinion to the full extent, but he admits the value of the observation as approximative. Thus he thinks we may hope for a perfect cure, when the paralysis has succeeded contraction; also a complete though tardy cure may be expected when it has come on after chorea, or in the course of an attack of fever. The case is more hopeless when the paralysis is preceded by convulsion; so also when the paralysis is gradual in its approach. The result is but little influenced by the part affected. Dr. West considers the prognosis to be greatly influenced by the duration of the affection at the time treatment is commenced. Of six cases of cure reported by him, four commenced treatment within two days of the attack, while eight, in

whom no treatment was adopted until the lapse of six months, remained permanently paralytic.

5. *Causes*.—Authors agree that this form of paralysis is more common in the first and second years of life than subsequently. In two-thirds of the cases on record, the child was between the ages of six months and two years. However West, Kennedy, and Heine, have known the disease to attack children as late as five, six, and seven years of age. Sex has no influence on the disease. It is more likely to occur, in the opinion of some writers, in robust and well formed, than in feeble and ill-nourished children, but such is not the author's experience. Among the occasional causes may be mentioned chills and blows.

6. *Diagnosis*.—The diagnosis of paralysis is not difficult, but it is not always easy to say whether the palsy is essential, or symptomatic of lesion of the nervous centres, unless the symptoms of the latter diseases have been well marked. The diseases of the brain which commence in convulsions at the age most liable to essential paralysis, are meningitis, tubercular hydrocephalus and meningeal apoplexy. The two former diseases are generally accompanied by disturbances of the sensorium, which are not seen in simple paralysis, and are moreover generally mortal. The same may be said of meningeal apoplexy, which is moreover commonly followed by tonic contraction of the limb. M. Ozanam believes that meningeal apoplexy is the cause of all the cases of paralysis, which are preceded by convulsions, but he does not adduce a single fact in support of his theory.

This form of paralysis can be confounded with diseases of the hip only by a very careless observer, and from the progressive muscular atrophy mentioned by M. Aran, it is distinguished by the latter being an affection peculiar to adult life.

7. *Treatment*.—West and Kennedy trust to purgatives and tonics, but allude entirely to the treatment of the stage of simple paralysis. Heine goes deeper into the subject, and endeavours to remedy the stage of atrophy also. The indications of treatment proposed by him are:—

1. To awaken the nervous power of the spinal marrow and nerves of the affected limb.
2. To restore the deformities by orthopedic measures.
3. To invigorate the constitution.

For the fulfilment of the first indication he gives nux vomica internally, and applies it in frictions along the spine. Electricity has failed entirely, but he has been more successful by well regulated gymnastic movements of the wasted limb. For this purpose various ingenious instruments have been devised which our space will not allow us to particularize.

GERMANY.

On the Nature and Treatment of Noma.

In a memoir by Professor Albers (*Archiv. für Physiologisch. Heilkunde*,) we find some valuable observations on the frightful disease known under the

title of *noma*, or *cancrum oris*. The author expresses his belief that there are two forms of the malady; one characterised by *soft*, and the other *hard* gangrene. In the first form the cheek becomes bluish, and sloughs away in layers, leaving a soft pultaceous surface, from which a sanious and horribly foetid pus exudes. This is a rare form of disease according to M. Albers, and should be distinguished from true *noma*.

The second form commences by a greyish-white induration of the submucous tissue of the cheek which soon becomes perceptible externally, and eventually sloughs to a greater or less extent. The author gives only a single example of this form, but enters minutely into its pathological anatomy. The first change which is perceived is an infiltration beneath the mucous membrane, which speedily coagulates, and gives rise to the induration above mentioned. The microscopic elements consist of fat granules, albuminous corpuscles, and dark bodies, the nature of which is undetermined. The blood-vessels manifest important lesions; their parietes are thickened, and their canals obstructed by coagula, but these appearances are the consequence, and not the cause, of the gangrene. The affection, he thinks, is evidently of constitutional origin, and the treatment must therefore include attention to the general powers of the system. The local measures advised are the application of mineral acids. The author makes no allusion to the value of chlorate of potash in this disease.

Another New Remedy for Tania.

There is a plant called *Muscuna*, a native of Abyssinia. M. Prunerby (*Neue Med. Chir. Zeitung*) professes to have used it in several cases with complete success. He was first apprised of its value by an interpreter, a native of Gondar, who had experienced its benefit in his own person. Its action differs from that of the *koussou*, inasmuch as it destroys the worm without inducing diarrhoea. It is given in the form of powder of the root, the dose being an ounce, taken fasting.

General Retrospect.

PRACTICAL MEDICINE AND PATHOLOGY.

Agave Americana in Scurvy.

This plant has been successfully used in America, by Dr. Glover Perrin. He states that while in the Texas several soldiers of his regiment became scorbutic. Of these, some were put upon lemon juice, others on citric acid, which were continued for several days without benefit. Being informed by the curate of the town that he had once suffered from an attack in his own person, and had been cured by the use of domestic remedies, among which was the agave, Dr. Perrin determined to make use of the expressed juice of this plant. A few days after its administration was begun, a decided amendment was observed, and all were soon relieved. The countenance, he says, so universally dejected and despairing in the patients affected with

scurvy, is brightened up by contentment and hope in two days from the time of its introduction, and there was marked evidence of improvement at each successive visit. Dr. Perrin, consequently, places this plant far above lime-juice as a remedy in this disease. The plant grows indigenous in most parts of Texas, and, he was informed, of New Mexico and California. It grows in a sandy soil, and contains a large amount of vegetable and saccharine matter, and is of itself sufficiently nutritious to sustain a patient for days. The manner in which it is used is as follows:—The leaves are cut off close to the root; they are placed in hot ashes until thoroughly cooked, when they are removed, and the juice expressed from them. The expressed juice is then strained, and may be used thus or may be sweetened. It may be given in the dose of two to three ounces three times daily.—*New York Journal of Medicine*.

New Method of Determining the Amount of Urea in Urine.—By Professor LIEBIG.

This consists in the addition to the liquid of a measured quantity of a solution of the nitrate of binoxide of mercury, which forms with urea an insoluble salt, consisting of one atom of nitrate of urea to four of the binoxide of mercury. It is only necessary to neutralize, by some alkali or alkaline earth, the nitric acid disengaged by the action of the urea upon the reagent applied, without which some of the precipitate would be redissolved. This method appears at once the readiest and most exact that has been yet proposed for the determination of urea, and by suggesting it, Baron Liebig has added materially to the services already rendered by him to animal physiology, in thus enabling medical men to watch with precision the changes that occur in this important constituent of the urine, whether in health or in disease.—*Medical Times and Gazette*, February 28th.

Correspondence.

THE INCOME-TAX.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—Will you oblige the Income Tax Committee of the Provincial Medical and Surgical Association, by inserting the enclosed letter in the current number of your journal. You will also confer an especial favour upon the Committee by seconding their appeal to the members of the medical profession, as they are anxious to induce all who feel aggrieved by the tax to range themselves under their banners.

I have the honour to be, Sir,

Your obedient Servant,

THOMAS SMITH, M.D.

Portland House, Cheltenham.

March 15, 1852.

To the Members of the Medical Profession.

GENTLEMEN,—The time has now arrived when it behoves the members of the medical profession to bestir

themselves, in order that they may prevent a re-imposition of that most hurtful measure, the Income-Tax. The Committee appointed at the Annual Meeting of the Provincial Medical and Surgical Association have had under their serious consideration the best method to be adopted to accomplish this most desirable object. They wish to apprise their professional brethren generally that an opportunity of making their grievances known to the members of the Income-Tax Committee of the House of Commons will shortly be afforded, and also that the Chancellor of the Exchequer has kindly consented to receive a deputation from the Association's Committee as soon as the state of public business will admit. Unless personal apathy or indifference should prevail, it seems impossible to believe that the Chancellor of the Exchequer would propose, or the enlightened Members of the British Legislature sanction in perpetuity, a tax so peculiarly unjust and injurious in its effects on the medical man. Upon no class of persons in Her Majesty's dominions has the pressure of the Income-Tax been so severely felt as by the medical profession. Forced at the outset of his professional career to maintain a respectable appearance, and compelled by popular prejudice, in the majority of instances, to form a matrimonial alliance ere he has fairly obtained a sufficiency to support even himself, after years of toil, with an in increasing family, the medical man rarely finds himself possessed of more than a bare competency to meet his current expenses, of which, by death, or the casualties of sickness, &c., &c., his dependent relatives may suddenly be deprived. When it is considered how large a portion of the medical man's time for ten, or it may be for twenty, years of his practice, is devoted to gratuitous objects, and how important it is to his future prospects that his professional income, based in public estimation upon his eleemosynary services, should be concealed from the public gaze, it cannot be wondered at that inquisitorial investigations, set in motion by the machinery of the Income-Tax, should be regarded by the medical practitioner with feelings of the most intense dislike. The exposure, consequent upon this tax, of his private affairs to the Income-Tax Commissioners, and a host of subordinates, cannot fail to induce most unpleasant forebodings in the honest mind; nor can it be concealed that those who are in possession of the knowledge of the *private* receipts of the medical man, however estimable they may view his character in *private* life, are not likely to consult him unless he can show a large balance in his Income-Tax returns.

The Committee of the Association, therefore, deem it to be their duty to inform the profession that they are determined energetically to oppose the re-enactment of this impost. They suggest the propriety of immediately assembling the local committees, and call upon every medical man, whether he is a member of the Association or not, to co-operate with them in their exertions to accomplish the above object; they wish to inculcate in every breast the necessity of a vigorous and united effort to relieve themselves from this intolerable grievance. They appeal to the few opulent members of the medical profession to whom the payment of an Income Tax may be of little consideration, to come forward and aid the Committee in their endeavours to obtain redress for the vast majority of

their brethren to whom the tax is most invidious, and the *abolition* of the highest importance. To the latter they would simply say—"Be up and doing." In order that all may act in concert for the general weal, the Committee would be glad to receive any information touching the oppressive nature of the tax—any instance indicative of its injustice, or any case detailing the injurious effects resulting from the measure. The Committee will be happy to receive suggestions, emanating from any medical man, as to the best mode of proceeding in furtherance of their object. They will be thankful for the names of those who are willing to come forward and volunteer evidence before the Committee of the House of Commons. They will feel greatly obliged to any medical man, whose engagements will not permit him to take a more active part, to communicate his opinions to the Secretary of the Committee. And, lastly, should any individual desire that the *facts only* of his letter be made known, his communication will be regarded as confidential, and his name not allowed to transpire. As the Committee are desirous to enlist every qualified member of the medical profession, and to obtain information from all, they would be glad to receive any communication upon this subject, to be addressed to their Secretary, Dr. Smith, Portland House, Cheltenham. It is of the greatest importance that the Committee should be prepared with their evidence when called upon for it; no time should be lost; they therefore earnestly hope that members of the profession will not delay their responses to this appeal.

Signed on behalf of the Committee,
THOMAS SMITH, M.D.,
Honorary Secretary.

ON THE VARIETIES OF CRANIAL PRESENTATION.

To the Editors of the Provincial Medical and Surgical Journal.

GENTLEMEN,—In the last number of your journal a communication appeared from Mr. Ogle, Student of Medicine, Edinburgh, in reference to my paper "On the Varieties of Cranial Presentation." As two or three passages in my paper have been misunderstood by Mr. Ogle, and one in particular has not been correctly quoted, I feel that some reply in explanation is necessary. Mr. Ogle lays much stress, *in limine*, upon an error which I have made in some statistics of Dr. Simpson's, whom I have "cited as an authority which will support my views." I showed, in the last number of the *Journal*, that I could scarcely be held responsible for the error in question, as it first occurred in the *British and Foreign Medico-Chirurgical Review* for January, 1851, and has been allowed to remain unnoticed until the present time. The views which this error would tend to support are not my own only, but those of nearly all the French accoucheurs; but I am prepared to support them, as well as any that are exclusively my own, by statistics deduced from my own experience, without the aid of those derived from other quarters.

In quoting one passage in particular from my paper,

Mr. Ogle has omitted two words, which materially alter the meaning of the sentence; thus, I am made to say, that "the second presentation is in every way similar to the first," whereas the original sentence stands thus:—"There is every reason, *a priori*, for supposing that the second presentation, which is in every way *the most* similar to the first, should be next to it in frequency." This sentence, of course, implies that, of the four presentations of the head, the mechanism of the second most nearly resembles that of the first; and this conclusion was based upon twenty-eight cases of the second position, in only two of which was it a result of a change from the fourth. I am thus induced to coincide with Velpeau, who remarks:—"La tête exécute les mêmes mouvemens, présente la même circonference aux divers plans du bassin, offre les mêmes diamètres aux diamètres principaux et aux axes des détroits, etc. Seulement, la fontanelle occipitale est inclinée à droite, au lieu d'être tournée à gauche."

I can by no means agree with Mr. Ogle in his estimate of the difficulty, and often impossibility, of the head passing through the pelvis in the fourth position. I do not draw this conclusion, as he would seem to infer, "from a comparison of dried pelves and crania," but from the results of six cases of the fourth position which I have witnessed, in all of which delivery was accomplished without difficulty, although the head continued in that position throughout the labour. Nor is it correct to suppose that a dried cranium would pass through a pelvis of a given size with much greater facility than a recent one covered with its integuments, for it is impossible to make any alteration of consequence in the shape of the former without fracturing it, whereas it is a matter of common experience that the shape of the latter may be considerably modified by the pressure exerted upon it during labour. Mr. Ogle takes exception to the words "very great," as applied by me to the "alteration which may take place in the shape of a child's head during labour;" and in support of his objection adduces some experiments of Baudelocque's, which were performed with a view to test the compressibility of a child's head. If, in referring to the account of these experiments, he had looked back a page or two, he would have seen a passage which, I think, fully justifies me in using the words "very great." It is as follows:—"We must not argue concerning the effects of the forceps from those which we see the head sometimes suffer in passing naturally through a narrow pelvis, because there is scarcely any parallel between the two cases; the form of the mould, which such a pelvis presents to the head being very different from that of the forceps, and the powers of art being never so gradual nor so well combined as those of Nature. The head pushed forward for hours together by the natural agents of delivery becomes insensibly softer and more pliable, and at length acquires the necessary dispositions for moulding itself to the form of the pelvis. If it then flattens in one direction it really lengthens in another; the form of the cranium only changes, and its cavity contracts so little that the brain is scarcely affected by it. I have taken children whose heads seemed to have lost nine or ten lines of their natural thickness in passing the superior strait, and seemed to have lengthened in the same proportion

without comprehending the tumour formed on the scalp, before the posterior fontanelle. The heads of several of these children were above six inches and a half, and even seven inches long, from the chin to the top of the aforesaid tumour; while the thickness from one parietal protuberance to the other was but two inches and a half, or two and three quarters in some and three inches in others. In a few hours after birth the heads of these children spontaneously recovered the thickness which they had lost in delivery, and lost the length which they had acquired by it. The head not only loses its form thus, in some cases, but sometimes even bends in the manner of a crescent, so that one of its sides shall be a little concave and the other rounded, without at all affecting the child's life."*

M. Baudelocque then adds, in a note,—"M. Solayres informed us one day in his lectures that he had taken a child the evening before whose head at the moment of birth was eight inches long all but two lines, measured between the two points indicated above; while it had preserved but two inches five or six lines in thickness. The day after, this head had recovered its usual dimensions."

I am, Gentlemen,

Your obedient Servant,

JOSEPH GRIFFITHS SWAYNE.

Clifton, Bristol, March 9, 1852.

THE NEW MEDICAL BILL.

To the Editors of the Provincial Medical and Surgical Journal.

SIRS,—I very much regret I could not be present at the special meeting of the Yorkshire Branch of the Provincial Medical and Surgical Association, held at the Philosophical Hall, Leeds, on February 26th, for the purpose of considering the "Draft of a Bill for Medical Reform." Permit me, therefore, to express my warm concurrence in the resolution proposed by Mr. Hey and Dr. Chadwick, and unanimously agreed to by the members then present. I hope measures will be taken at once to introduce the Bill into the House of Commons; and also that the resignation of office by Sir G. Grey will not prevent his taking charge of it. After the general approval of the profession and medical journals, there can be no good reason for preventing the Bill at once becoming the law of the land; and thus setting at rest a question which for many years past has agitated, injured, and divided the members of our profession. The sum of 20s. appears large for registration, but we must not forget the Medical Provident Fund,—an important feature, in my opinion, of the Bill, and one that ought not hastily to be given up. I think the alteration suggested at Leeds an important one, viz.,—"That all unqualified persons be prevented from giving evidence in Courts of Law." The other clauses of the Bill, which provide *uniformity of qualification for all when first entering the profession*, leaving them afterwards to go to the College of Physicians, or the College of Surgeons, if they think

* "Baudelocque's Midwifery," translated by J. Heath. pp. 369, 870.

proper to take a higher rank;—*for the expulsion of men who, by their evil deeds, have forfeited their character;—for an efficient registration;—and for the punishment of those who daily trifle with and sacrifice the lives of their fellow-creatures, by practising without any qualification,* can only obtain at the hands of the honest and honourable members of the profession an unanimous verdict of approval.

I am, Gentlemen,

Your obedient Servant,

JOHN CHARLES HALL, M.D.

Fellow of the Royal College of Physicians of Edinburgh.

Sheffield, March 6, 1852.

P.S. I would suggest that a petition in favour of the Bill be at once prepared and signed by every member of the Association.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I have perused with much pleasure the “Draught of the Proposed Bill for the better Regulation of the Medical Profession;” it is, without doubt, the best which has yet been framed, still it would be excellent with a few alterations. I have read the remarks of those who have freely spoken at the several meetings which have been held lately, as to its merits. The Bill proposes to make the fee for the diploma to practise medicine and surgery £10; instead of this, the fee in surgery should not be less than it now is, £22, and in medicine, &c., £10, for the country,—that is, for the licence from the Apothecaries’ Hall, if this Company are to be allowed to grant their licence, which, by the by, is scarcely valued after its possession, except as the law requires. It would, however, I conceive, be much better to do away with the examination at Apothecaries’ Hall, and substitute one before a court at the College of Physicians; or, if preferred by some, let a medical board be formed at the College of Surgeons, and such an examination held on a given day, besides the present one for the diploma in surgery. This would be considered more respectable by the public, for the name of “an apothecary” sounds offensively, and yet the man is nothing more than the humble apothecary until he also possesses the diploma from the College of Surgeons. Why should he? His licence states he is “*duly qualified to practise as an apothecary,*” not surgeon. Each one going into general practice should be compelled to undergo a double examination,—one on surgery, &c.; the other in medicine, chemistry, and midwifery.

It is well known there are now persons practising in England, in all the branches, with only a Scotch diploma, contrary to the Act of 1815, obtained by the Apothecaries’ Society. They have the same privileges and immunity as the fully-qualified practitioner here. There are others with only an English diploma in surgery practising generally, contrary to the above Act. Their knowledge in Latin, medicine, chemistry, &c., has never been tested by an examination; yet the authorities at the Hall take no steps to put down this illegal proceeding. They enact a law, receive the fees,

and leave their Licentiates to fight their own battles. I hope it will soon be said of them,—*delenda est Carthago*, unless they amend their manners.

I am, Sir, yours obediently,

B. W. BROWNE, M.R.C.S., Eng.

Wymeswold, February 28, 1852.

MR. NOBLE ON OUR INSERTION OF MR. HUGHES’S LETTER.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—In this day’s number of your Journal, I read the following observations, contained in a communication which you have inserted from Mr. William Hughes, of Chatham Street, Piccadilly, Manchester:—“The *Medical Times* states that all persons practising as Apothecaries, without the Apothecaries’ licence, are irregular practitioners. I am fully convinced that Mr. Noble is in the habit of meeting persons in consultation who have no legal medical qualifications.” If this statement signify, as to some, upon a hasty perusal it may appear, that I am in the habit of meeting, or that I have ever met, persons unqualified, I must give the assertion an indignant denial. If it mean, however, as I suppose it does, that I frequently meet surgeons in consultation who have no licence from the Apothecaries’ Company, I admit the fact, and beg to ask of you, Sir, who have published, and so far endorsed, the ridiculous accusation,—What then?

I am Sir, your obedient Servant,

DANIEL NOBLE.

Manchester, March 3, 1852.

[We certainly do not consider that we endorse all the letters inserted by us, as there are many with the sentiments contained in which we totally disagree; but we do consider ourselves bound to insert any properly-expressed communication from a person whose conduct has been in any way animadverted upon in these columns. Such was our reason for the insertion of Mr. Hughes’s letter, of whose character or practices we knew nothing whatever; and as his charge against Mr. Noble is perfectly ridiculous, we did not think that gentleman would do more than laugh at it; whilst its insertion has put it out of Mr. Hughes’s power to say that he had been refused the Englishman’s privilege of a defence in open court. In coupling Mr. Noble’s name with Mr. Hughes’s, we thought that we were only connecting a gentleman of high standing with a student who had been prevented from taking his diploma by the want of pecuniary means. If, however, Mr. Hughes’s position is of a different complexion, we regret exceedingly that we should have unwittingly subjected our respected associate to such a degradation. —Ed. J.]

TREATMENT OF THE INSANE.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I was about to write to thank you for the honor you did me in inserting my letter of the 1st of November in your journal, and to explain the principles and objects of the Alleged Lunatic’s Friend Society, with regard to the law for the confinement of private

patients alleged to be insane, when one of the members of your Association, who has taken a warm interest in the proceedings of this society, forwarded to me an extract from your number of the 10th of December, containing a letter dated the 28th of November, and signed by an "Associate Member of Council," in which you are strongly, and I think unfairly, remonstrated with, for having suffered my letter to appear in your columns, in consequence of what he terms "the invidious charges which I make at the close of my letter against a body of gentlemen, members of the medical profession, and associates of a society of honourable men."

Whilst preparing a reply to that letter, my friend also forwarded to me another letter of your correspondent, E.B., in reply to part of my letter, and since then, a letter of a very different order, from an "Admirer of Truth," upon the same subject. I will endeavour, with your permission, to notice these three communications, although I am afraid that in justice to the value of your space and time, I must very much condense my observations, and omit much which I could adduce to enforce my opinions; I find myself also in some difficulty in addressing a medical journal, the subscribers of which are so jealous of reflections upon the conduct and practices of a body of men, the majority of whom certainly form, I believe, a branch of their profession, of whom, I confess, *from my own experience* and from that of others, I entertain very strong opinions.

With regard to your correspondent E.B., I will only observe, that the assertion which he makes that he made no allusion to my name, as the report to which he alluded to was signed by other gentlemen besides myself, is like other of his remarks, incorrect, and I conclude from this additional inaccuracy that he has not read the report himself, or that he has only done so very hastily. For if you refer to it you will find that it only bears my signature, though it is headed by the names of other members of the Society, who, however, are not, for the most part members of the committee, and, therefore, had nothing to do with the drawing up of the report. I must also decline accepting his compliment to the amiability of my disposition at the expense of my credit for sound judgment *in these matters*. The rest of his argument I am inclined to leave to his able antagonist, Dr. Henry Munro, to deal with; not that I entirely concur in all his suggestions for improving the inspection of asylums, but that he admits in principle the necessity and propriety of such inspections, whilst he agrees with E.B. and with myself, that the inspection is not satisfactory; which proves that one of the complaints of the Alleged Lunatic's Friend Society, is founded on proper and sound judgment, and that, consequently, so far at least, the Society is worthy of the respect and support of my fellow-countrymen.

In the letter of "An admirer of Truth," I will only notice two passages, as my answer to "An Associate Member of Council" will furnish a reply to his general argument, that principles of enlightened self-interest are sufficient to guarantee society against the abuses to which I contend that the present system of private asylums is of its own nature liable. The first passage is, "that enlightened self-interest, guided by science and spurred on by a moderate com-

petition, will eventually accomplish a larger measure of success in the treatment of the insane than is likely to result from purely eleemosynary means." If he means by eleemosynary establishments—public asylums, supported by county rates, under the sole direction of the magistrates or of the government, I desire to state that this opinion, supported by the opinion of the late celebrated Dr. Esquirolles, with whom I had a conversation in Paris upon this very point, for a long time kept me decidedly adverse to the abolition of private asylums, to such an extent, that when the committee of the Alleged Lunatic's Friend Society adopted a report, recommending their abolition, I considered it my duty to publish a letter to the members of the Law Amendment Society, who were then discussing the subject, deprecating such extreme views, and this letter very much influenced the report of that Society, or at least its principal views were adopted by them. Recent experience and observation, however, in the treatment of a friend, and the reports of the visiting magistrates of the county of Gloucester, and the memorial to the Commissioners of Lunacy from a patient, respecting the management of an asylum of great show, if not of great repute, in this neighbourhood, have very much shaken me in this opinion. My mind is now, (perhaps weakly,) in suspense upon the subject; but I could no longer offer any cordial opposition to the proposition for abolishing private asylums, or, which I think the best plan, for remodelling them, so as to make the proprietors of them officers of government, with fixed salaries, though I might still hesitate to originate such a measure. At any rate, this statement will, I trust, remove from me the suspicion that E.B. attempts to throw upon my judgment, that from prejudice or wild enthusiasm I am reckless and hasty in coming to my conclusions on this delicate and difficult subject; whilst it shows that I have the moral sense of duty and the courage to oppose even my friends, when I think they are likely to lead government into error, or, to use a homely phrase, ready to jump from the frying-pan into the fire.

With regard, however, to charitable institutions, properly so called, I have always been of opinion that such hospitals, under the proper control of government, who in return should contribute, as they are bound to do, for their support, are the most proper sort of establishments for the insane; always premising that they should not be too large, and that they should be managed by a committee elected by the governors. I say not too large, because I think every medical man will agree with me in stating that it is only moral or economical necessity, that justifies the amassing together a number of nervous patients of every character, for I class all kinds of insanity under the head of that indefinite and little understood term "*nervous*" disorder, and exposing them to the exciting or depressing influences of their conduct and appearance one upon the other. The more such patients can be kept quiet and separate, and in cheerful circumstances I hold to be the better; and the best institution I have heard of, of this nature in principle, (I do not know how it answers in practice,) is one in Belgium, where the patients are placed as lodgers in private houses in a large district, under the inspection of civil and medical officers, and, where the owners of houses forfeit their licences to

receive patients if they are guilty of any misconduct. I should be glad to see such a system tried in this country.

The advantages of such hospitals are these:—That there is no temptation to any party to confine a person unjustly, or to detain them longer than necessary, unless we suppose that the governing committee are negligent, and the medical superintendent bribed. The management of such places by a committee of governors, secures attention to any reasonable complaints, and admits the prospect of suggestions being received for the amelioration of the treatment of the patients from humane and zealous persons; whilst the control of government affords also some guarantee against abuses in the personal treatment of patients, in the misapplication of their property, and in their being confined improperly for legitimate opinions, which may only appear to be insane because they militate against received notions, strict prejudices, or surpass the understandings of the medical officers and governors. Such opinions, for instance, as those of the founders of Christianity appeared to be in their day—as those of Galileo, or those of the originator of the railroad system, who were all in their turn looked upon as maniacs and visionary enthusiasts.

The next passage in the letter of “An Admirer of Truth” is the following, in which he, too, much corresponds in one respect with E.B., who can see no defects in our present law but such as appear to militate against the interests of the proprietors of asylums. He writes:—“I also consider the last Act of Parliament on the subject about as perfect as human laws in the present state of the world can be.” Now, what did Lord Ashley (now Lord Shaftesbury) say in Parliament last year with respect to this very law—a law which he introduced himself, and arrogantly carried through the House of Commons, in spite of every opposition from my friends and myself, and demonstrations of its necessary failure, and petitions for referring the question before hasty legislation to a committee of inquiry. In the debate on Mr. Lang’s motion, to place religious houses under the inspection of the civil authority, a motion sound in principle, and which in respect to his own Protestant opinions he was bound to encourage and support, rather than baffle, but which, with an inconsistency of conduct too common with him, he aided in setting aside; he declared if the motion was founded on the law for the inspection of lunatic asylums, *nothing could be more defective!* What, I may observe, could more stultify his Lordship and prove his incapacity to meddle with this subject, on which he enjoys, unfortunately, such pre-eminent confidence, than this admission? And what more could be said, or on what greater authority, in justification of the position which the Alleged Lunatic’s Friend Society has taken up? I do not say of our views, for these are points on which we invite discussion. We do not dogmatise: our petitions have always been for an inquiry, and it was only at the desire of a member of Parliament that we drew up a Bill for him to introduce into the House of Commons, in which we by no means pretended to be perfect, but which we hoped to have been made more perfect in committee. Such, however, is Lord Shaftesbury’s own opinion of this *perfect* law. I do not know what to conclude from it as regards my own

opinions, on account of the remarkable inconsistency of his Lordship which I have before alluded to. But I would ask “An admirer of Truth,”—Is he an Englishman, and is he a Christian? Am I dealing, as I hope I am, with a person of good faith? If he is an Englishman, and values the great and noble principles of our Constitution, how can he call a law perfect which admits of the seizure of men, and still more of females, who are more defenceless, by the servants of the proprietor of an asylum, with or without the assistance and evidence of the police, at any hour of the day or night. I know an instance where a young man was lately seized in his bed, at three o’clock on a November morning, upon the order of a relative *or stranger*, (as the Judges have expounded the law), upon the certificates of two medical men of any degree, from a physician to an apothecary, of any age, of any character, of any stamp in their profession, upon charges made behind their backs, and not communicated to them, unless it is the pleasure of the parties who so deal with them to do so; and allows them to be confined without the sanction of any kind of tribunal, even of a magistrate, and when confined to be cut off from all correspondence with their friends, or any parties likely to assist them, except the visitors of the asylum, whose inspection is now admitted on all sides to be insufficient, and who may not visit the asylum for three months, or even longer, after their confinement. If “An admirer of Truth” is an Englishman, can he call a law that admits of such treatment a perfect law, and retain his reputation for sound faith or sound judgment? And if he is a Christian, and acknowledges the obligation of the precept to serve his neighbour as himself, can he uphold a system to which, if he was himself subjected, he would be the first to apply the terms of the most revolting tyranny. God forbid that I should wish my bitterest enemy to become insane, to know the degradation and horrors of such a state of mind, and all the miseries and anxieties entailed upon a man afterwards by such a calamity;—the weight and agonies he must carry down with him and be tried with, to his grave; but I acknowledge I should be glad to see some of the proprietors of asylums confined *on false charges* of insanity, that they might be able to appreciate the injustice of such a system, and all its painful and dangerous consequences. And permit me to say, that with all the respect which I have to the medical profession generally, and particularly to many of them personally, with whom I am more or less intimately acquainted, so long as they accept with complacency such a law, and speak of such a system as perfection, without any resentment of its oppressive nature and injurious results to the moral sentiments, to the mental faculties, to the fortunes and reputation of those who may be improperly subjected to it, whether from malice or by mistake, I cannot look upon those engaged in such a system without suspicion, and upon the general body of the practitioners without mistrust. Let me also observe, that it is against this system that my efforts and those of the Alleged Lunatic’s Friend Society are chiefly directed. The question is *not* the private character, but the official conduct of proprietors of asylums; and of the merits of private asylums, however important, is a different question. Were the conduct

of the owners of such establishments, so to say, beyond suspicion, I should still condemn a system which depended only upon individual character as a security against abuses; and the painful duty of exposing the nature of the conduct of these gentlemen, in too many instances, is only forced upon us by those who appeal to their high reputation and impeccability as a reason for casting suspicion upon the complaints, and deriding the apprehensions of those who have escaped from their authority, and as an argument for acquiescing in a vicious state of the law, from which, however much it must be admitted, no evil consequences are likely to follow.

I have already been compelled to trespass, I fear, too much upon your valuable time and attention, and I must reserve my observations upon the letter of "An Associate Member of Council," if you will allow me, to another opportunity.

I have the honor to be, Sir,
Your obedient humble servant,
JOHN PERCEVAL.

Kensington, Feb. 25, 1852.

Medical Intelligence.

QUEEN'S HOSPITAL, BIRMINGHAM.

At a recent meeting of the Committee of Council of the Queen's Hospital, Dr. David Nelson resigned his office of Physician to that Institution. At the same time the Committee of Council passed a vote of thanks to Dr. Nelson for his past services to the charity.

APPOINTMENTS.

Mr. W. Wright has been appointed Surgeon to the Whitehaven and West Cumberland Infirmary.

His Excellency Lord Cowley has appointed Dr. Olliffe Physician to the British Embassy at Paris.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on February 27th:—Robert Beales, Leicester; Edwin Bennett, Dorchester; Edward Henry Fitzhenry, Liverpool; Richard Gregory Cornall, Newton Heath, Lancashire; Walter Jessop, Cheltenham, Gloucestershire; John Page Julian, Little Blakenham, Suffolk; John Lumsdaine, Hon. East India Company's Service; Edwin Josiah Miles, Gillingham, Dorset; John Norton, Kennington; John Pring, Bristol; Septimus William Sibley, Great Ormond Street; James Kemp Welch, Christchurch, Hants; J. Pleydell Wilton, Gloucester.

The following gentlemen were admitted on the 5th instant:—Aaron Atkins, Mile End Road; Bernard Charles Beale, Bedford Square, Steyney; James Henry Crisp, Bath; Charles Goring, Demerara; William Phillips Kirkman, Woodbridge, Suffolk; James M'Cann, Parliament Street; Charles Thomas Paske, Hon. East India Company's Service; Wm. Pilkington, Leyland, Lancashire; Samuel Rhind, Ross, Herefordshire; Stephen Walmsley, Liverpool.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, March 4th:—John Breay Butcher, Devonport; Thomas Habbes Cresswell.

SOUTH-WESTERN BRANCH.

At a special meeting of the SOUTH-WESTERN DISTRICT BRANCH of the Association, held at the Exeter Dispensary, on Wednesday, March 10, for the purpose of considering and discussing the "Draft Bill for Medical Reform," P. W. Swaine, Esq., of Devonport, the President, in the chair, the various clauses of the Draft Bill having been duly considered and discussed,

It was resolved unanimously,—

"That in the absence of sufficient information, this meeting desires to suspend its opinion relative to clauses 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12.

"That the following alterations and additions be recommended in clause 15:—That, 'for a period of four years' be substituted 'for a period of not less than five years'; and that the following regulation be added—viz., that no pupil be admitted to an University, or other regular School of Medicine to hear lectures unless he shall have previously undergone a matriculation examination to prove that he possesses sufficient elementary professional knowledge as will enable him to profit by the course of study established in such school or University; and this meeting strongly urges this suggestion upon the attention of the Central Council, as it would render highly profitable a period of time too frequently turned to little account in the acquirement of knowledge, practical and theoretical, and would also prevent the necessity of such expenditure of time and money at the metropolitan schools as is contemplated by the present clause.

"That in regard to clauses 17, 18, and 19, the following be introduced, viz.:—That certain trustees be elected from the general body of the profession, in whom shall be vested the power of disposing of all surplus monies, whether derived from fees arising from registration, examination, or from penalties; and that such trustees shall not be members of the Council or of the Examining Board.'

"That this meeting entirely approve of all the clauses referring to registration and penalties.

"That the best thanks of this meeting be given to the Committee of the Dispensary for their kindness in allowing the Association the use of their room.

"That the best thanks of this meeting be given to the President, P. W. Swayne, Esq., for his able conduct in the chair."

W. D. KINGDON, M.D., Secretary.

Exeter, March 10, 1852.

TO CORRESPONDENTS.

Communications have been received from Mr. Solomon, E. B., Nil Desperandum, Chirurgus, Mr. Ikin, Birmingham Pathological Society.

A Member, Wellington, Somerset, is informed that the usual fee paid for the medical examination of a pauper lunatic under the Act 8 and 9 Vict., is one guinea, increased according to the distance from the residence of the medical examiner.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

OPHTHALMIC SKETCHES.

SHORT LECTURES

DELIVERED TO THE

STUDENTS ATTENDING THE BIRMINGHAM EYE INFIRMARY.

By JAMES VOSE SOLOMON, M.R.C.S.,

One of the Surgeons to that Charity, lately Surgeon of the Birmingham General Dispensary.

LECTURE II.

CONTENTS.—*Foreign bodies on the cornea; mode of examining the eye, and controlling its movements; circumstances which influence the detention of foreign bodies upon the cornea; proper instruments for their removal.*—CASE II. *Corneitis and scleritis induced by the detention of a particle of steel in the corneal substance; the methods which Nature takes to prevent the irritation of an impacted body; escape of aqueous humour after the extraction of a foreign body; treatment.*—CASE III. *Anaurosis resulting from the non-removal of a small piece of iron from the cornea; injuries of the cornea from gunpowder; treatment.*

GENTLEMEN,—In my last lecture I stated that it is necessary, in looking for a foreign body, to view the eye obliquely, as well as in front. This is absolutely required when a small dark-coloured foreign substance lies upon that part of the cornea which is opposite the aperture of the pupil. A body so placed, if otherwise viewed, will be undiscernible. The patient should be seated before a bright light, a northern aspect is preferable, and the surgeon should stand behind or on one side of him, having satisfied himself of the presence and situation of the intruded substance. He takes his position at the back of the patient, whose head he allows to rest upon his (the surgeon's) breast. He now elevates the superior palpebra with his forefinger, and fixes it firmly against the superciliary ridge, while with the second finger of the same hand he depresses and maintains the inferior palpebra against the lower ridge of the bony orbit, at the same time making gentle pressure upon the globe, so as to control its movements. With the disengaged hand he removes the foreign body, having previously selected a proper instrument for that purpose. A small lens is of great service in discriminating foreign bodies upon the cornea, which in appearance sometimes simulate a laceration of the epithelium corneæ. An assistant should hold the lens at a proper focus, so that the operator may look through it when he undertakes the removal of the intruded substance. Foreign bodies may be temporarily retained in their position upon the cornea by (a) adhesion,* by (b) entanglement in the corneal epithelium, by (c) penetration into the substance of the cornea, and by (d) an effusion of lymph. If either of the two first conditions, or the last (a, b, d) should be present, the foreign body will be readily removed by a silver toothpick† or a pointed probe. When the

third condition (c) is present a curette, or a strongly made and inelastic Scarpa's needle, will be a proper instrument. You insert its point beneath the metal, and gently elevate it. In some cases I find a pair of fine-pointed forceps will accomplish the extraction after the curette has failed. Rather than deeply lacerate or deface the cornea, it will be much better to leave the foreign body intact, until by ulceration its attachments shall have become loose. The following case will further exemplify the pathology of these accidents:—

Case 2.—Phœbe Ballard, aged 21, a gimlet maker, of phlegmatic temperament, applied to me on the 26th of November, 1842, to remove a piece of steel from the centre of the left cornea. I succeeded in detaching the more prominent portion of it, but a part remained deeply imbedded in the substance of the cornea. The patient was immediately relieved, by this procedure, of all pain and irritation, and continued to be so up to the evening of the 5th of January, 1843, (six weeks from the date of the accident,) when the injured eye "felt as if it would burst." It was inflamed, and the vision dim.

January 12th.—She came to my house in great alarm, complaining of severe pain in the globe of the eye, forehead, and malar bone. The cornea was so opaque, that upon closure of the opposite organ she was unable to discern any object; it had an appearance like unto ground glass, upon which aqueous vapour had been condensed. The fragment of metal lay loosely on its surface, and was easily removed by a blunt probe. The conjunctiva and sclerotic were acutely inflamed. The vapour of concentrated hydrocyanic acid was applied three times on that day, and on the next morning I found the cornea clear, but suffused with tears, and surrounded by a very narrow and pale-red ring. She resumed her work the same day, and continued well.

What do we learn, gentlemen, from the preceding case? First, that a foreign particle may lie for six weeks in the substance of the cornea without exciting irritation; and then, either by change of its position, or some influence acting from within or without the patient's body, may induce violent inflammation of the textures of the globe. Secondly, that upon the removal of the exciting cause the effects rapidly subside. This is the only case of acute ophthalmia in which the fumes of concentrated prussic acid have been attended, in my hands, with decidedly beneficial results, and I at one time made trial of this agent in a great variety of ophthalmic affections.

I have already adverted to a method by which Nature disengages the hold of foreign substances upon the texture of the cornea, by the ulceration of parts immediately in contact with them; the metal, if of pure iron, at the same time loses its angularity, and wastes by undergoing oxydation. It is very probable that in this way, aided by the continual brushing (niction) of the eyelids, and lachrymal irrigations, many of them, which were originally impacted, are swept from the surface of the cornea. The frequency of applications to remove supposed substances, that are really only

* Adhesion is here used in the physical, not in the surgical sense.

† Heister's surgery.

the brown stains left by oxydated metal, once lodged in their situation, supports this opinion.

There is yet another way in which the *vis medicatrix naturæ* protects the delicate tissue of the cornea from injury, which is, by encasing more or less completely, a small foreign particle lying upon the surface of the cornea with lymph; it then has the appearance of an ulcer, unattended by vascular excitement, upon which an excess of lymph has been deposited for its repair, and has often been treated as one. The observation of one or two cases will familiarise your eye with its characteristics; if you have any doubts, the aid of a powerful lens will satisfy you. Very often I have been able, with the naked eye, to discover the foreign substance, by its colour, in the midst of the lymph.

Interference with a small body, deeply driven into the cornea, may occasion an effusion of the contents of the aqueous chamber, the iris will then approximate the wound, and may, it is said, if care be not taken, become adherent to the aperture. In such an event the wound being near the centre of the cornea, you should immediately introduce a solution of atropine or belladonna upon the surface of the eye, place your patient in a *darkened* chamber, and give him a filtered collyrium of belladonna, (dr. ss.—oss.), to bathe the eyelids with every hour, so as to insure full *dilatation* of the pupil. Should the wound be remote from the corneal centre, you should make gentle friction upon the globe with the thumb placed over the superior lid, and suddenly expose the eye to a bright light, to induce *contraction* of the pupil, then wait a few hours for the re-formation of the aqueous humour, and afterwards, if necessary, touch the puncture with a stick of finely-pointed caustic. Spirituous oriced lotions should be applied from the first occurrence of the accident. If, from inexperience upon your part, or restlessness on that of the patient, there should be a difficulty in applying the caustic with precision, it will be better for the patent part to be touched by a small hair-pencil, charged with a twenty-grain solution of the nitrate of silver. When the aperture is small, there is not much danger of the iris becoming adherent.

A modern author recommends, if the foreign body "be small," and do not excite irritation by projecting from the surface of the cornea, and in the event of your dislodging it there be "a risk" of the occurrence to which I have just adverted, that "it should be allowed to remain, and fall into the anterior chamber, for in these instances, before the foreign body falls into the anterior chamber, deposition on its exterior will have occluded the opening which its entrance produced."

I have never seen a case in which a small *impacted* substance, capable of being skilfully extracted, took such a course, indeed the oxydation of the penetrating point, (if of iron,) by contact with the aqueous humour, the ulceration of the superficial layers of the cornea already spoken of, and the extraordinary resistance to such degeneration, possessed by the posterior elastic lamina of that membrane, render the occurrence improbable. In the case of Ballard, the piece of gimlet "was of small size," and did not excite any irritation

whatever for six weeks, a period fully sufficient for the theory quoted to have been verified; and, supposing the intruded substance does so deeply enter the tissue of the cornea as to gain admission to the anterior chamber, and become coated over by lymph or corneal tissue, it will appear, by the case I am about to relate, that it does not necessarily follow it shall fall into the anterior chamber, or even that the functional integrity of the organ shall be preserved.

Case 3.—Gideon Billingham, 28 years of age, of healthy constitution, whilst hoeing a row of potatoes, felt something to penetrate his right eye. He immediately applied to a surgeon, who operated upon the affected organ, which "became flat in its front," but resumed its natural form in about two hours. The patient was afterwards bled and "physicked." At the expiration of the third week of the treatment, (July, 2, 1851,) he applied to me at the Birmingham Eye Infirmary. There was some sclerottitis and conjunctivitis of the right eye; no zone round the cornea, which was transparent; iris, in colour and movements normal; pain in the brow. I was unable to discover any foreign body until the eye was viewed in profile, in which position a body one-tenth of an inch in length, in colour and calibre resembling a piece of black bristle, was noticed projecting from the concave surface of the cornea into the aqueous chamber. The body was too small and unfavourably placed to encourage the prospect of an operation being successfully performed by the aid of the instruments which our institution then possessed, (I believe that Luers capsule forceps, which we have since purchased, might have accomplished its removal.) I directed the temple to be cupped, counter-irritation behind the ear, and mercury to slight ptialism, from which treatment so much vision was obtained as to enable him to read for short periods.

August 30th.—Eight weeks and three days since the occurrence of the accident. Right eye much the same; complains of weakness of vision in the *left* eye, the pupil of which is dilated beyond the medium size, and contracts but slowly when suddenly exposed to bright light. Under treatment the eye recovered for a time, and again relapsed into dimness; no apparent change in its textures. By the 31st of October, the steel in the right eye had disappeared, leaving a brown precipitate in the substance of the cornea. The oxydation was most probably completed in the month of September. This eye now presents a greenish orange-coloured iris, a large black and fixed pupil, serious impairment of vision.

November 25th.—Vision in the right eye grows gradually worse; iris of a bright orange colour, pupil widely dilated. The pupil of the *left* eye has nearly regained its natural figure; the textures look healthy; the sight is so much improved that he can *now* read with it.

We have in this case an example of amaurosis from slow inflammation of the posterior tunics, creeping on to the iris, primarily induced, there can be little doubt,

by the irritation of the small particle of steel. The patient was fortunately in circumstances which permitted him to carefully carry out the treatment I recommended, which included perfect rest of the eyes. In analogous cases, where the patient has been obliged to continue his daily employment, the eye sympathetically affected has been seriously injured.

The rules, then, that I recommend for your guidance are:—To remove a foreign body impacted in the cornea whenever you can do so with facility; failing this, that you carefully watch the case until ulceration shall have loosened the foreign body; that, if you *anticipate* an escape of the aqueous secretion, you should dilate or contract the pupil, according to the situation of the impacted substance, *prior* to its removal. The treatment proper for an unforeseen loss of humour has already been fully detailed.

After the removal of a foreign body, it will be proper to enjoin perfect rest of the eyes, an unstimulating diet, fomentations, and saline purgatives; if there should be signs of corneitis and sclerotitis, the symptoms of which have been detailed in Ballard's case, (No. 2,) or of inflammation of the iris, indicated by a change in the natural colour and brightness of that membrane, and by little or no contraction in its pupillary aperture, when suddenly exposed to light, it will be, in addition, expedient and right to cup or leech the temple, to exhibit calomel and opium every four hours, and a mild aperient every morning. When the more acute symptoms have subsided, counter-irritation behind the ears, a small dose of calomel combined with Dover's powder every night, and a terebinthinate mixture; or, if the patient be strumous, five-grain doses of cinchona and soda, will, in the majority of cases, complete the recovery. In iritis, after bleeding, we apply extract of belladonna to the brow; and when the external ophthalmia has become subacute, a filtered solution of that drug or of its alkaloid (atropine) to the conjunctival surface.

A collyrium of belladonna (dr. ss.—oss.) may be used, either warm or cold, according to the feelings of the patients, from the first accession of the anterior internal ophthalmia. It is soothing to the inflamed organ, and when the acute symptoms have somewhat subsided, dilatation of the pupil, or, to speak physiologically, contraction of the radiating fibres of the iridal structure will be promoted by its application. I have spoken thus generally of the treatment to be employed in acute traumatic ophthalmia, because the subject will be more minutely considered when I treat of idiopathic inflammation of the various structures of the eye.

I have occasionally been called upon to attend persons who have sustained injury of the eye, from the explosion of fire works, or of gunpowder. The grains of powder lodge in the corneal substance, some of them passing through its texture, enter the lens, and occasion cataract; others penetrate the iris and occasion inflammation of that membrane. The lens and iris appear to shield the posterior internal tunics from serious injury. In the majority of cases which have come under my notice, the coats of one eye have been so

seriously damaged as to occasion sloughing and atrophy of the globe. If we see the patient, which is rarely the case in eye-infirmary practice, immediately after the accident, we should administer chloroform, and then detach as many grains of powder as is possible from the cornea, cleanse the surface of the eyes of all loose or extraneous matter, confine the patient to a dark room, and adopt an antiphlogistic regimen; meeting reaction by general or topical bleeding, or the two combined, according to the urgency of the symptoms and constitutional power of the patient. I have already adverted to the treatment of corneitis and iritis, it therefore only remains for me to remark, that after the symptoms of inflammation have apparently subsided, the gums should be kept *slightly* tender by mercury, and when the eye has become perfectly tranquil, the opaque lens may be operated upon in the usual manner practised in cases of soft cataract. If the pupil be closed, or very narrowly contracted by adhesions, the globe of the eye being of normal size and tension, an operation for artificial pupil may be undertaken with a reasonable prospect of success. The opacity of the cornea, which results from explosions of gunpowder, is generally maculated, and in a great measure subsides under judicious treatment.

CLINICAL LECTURES

ON THE

PRACTICE OF PHYSIC,

DELIVERED IN THE

THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D., EDIN.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c.

LECTURE XIII.

ON THE MORBID CONDITIONS OF THE DIGESTIVE ORGANS AND PASSAGES.

GENTLEMEN,—Digestion, in its larger acceptance, means something much more profound and extensive than what occurs within the mere involutions of the *primæ viæ*, and the cluster of glands which are more immediately attached to them. These, in fact, are but the first recipients of the cruder elements of assimilation, and the primary agencies which are brought to bear upon the great and hidden scheme of vital transformation; for, not merely until blood is formed, but until the more complex structures of the body are actually perfected, can we say that the true and ultimate transformation has been effected; for, even after the first assimilation has been completed, by the conversion of the dead elements into nutritive chyle, that chyle has yet to be converted by the lungs into true blood; nor would the blood itself be qualified to create or repair the various tissues of the body, unless a peculiar power of metamorphosis resided within each individual organ, by which the elements of this common source of

nutrition are so reacted upon that an almost endless variety of processes is made to conduce to an almost endless variety of productions throughout the animal economy. Such views of the subject were admirably illustrated by the late Dr. Prout, and, in his volume upon "Urinary Derangements," you will find a great fund of deep and accurate instruction.

On the present occasion, however, I mean to speak of the digestives only in their ordinary sense of primary assimilants, but I premise the above observations upon the matter because, as you will see, it would be impossible for you to thoroughly understand the significance of those secondary and tertiary symptoms which often constitute the evidences of a derangement in these primary parts, or to reduce, as it were, a multiform disease into unity, without constantly bearing in mind the manifold and complicated links by which each of these simpler parts are associated more or less with the most distant recesses of the general system. Indeed, it is not desirable, considering the structure of the human body, that any idiopathic affection, however apparently localised, should be viewed or treated without a regard to the whole framework, and much less so the affections of those all-important organs in which a failure of energy involves a failure of all other energies. It is only by the habitual exercise of such comprehensive modes of investigation, that any man ever disciplines himself into a really scientific and practical physician, who must obviously look as much to the rational as to the visible signs of bodily disorder.

This system of organs and passages begins, as you are aware, at the mouth, and terminates at the anus. It is a sort of inversion of the external dermis, now consisting of a simple passage of greater or lesser dimension, then of a more dilated sac, and again of deeper and more complicated foldings as it branches away from its simpler course, and forms itself into expansive and complicated branches of glandwork. Throughout it is covered with epithelial cells while in a state of rest, and underneath lies the mucous membrane, either elevated into minute glands, or dimpled into the smallest follicles or pouches for the secretion of mucus, gastric juice, and the like, or branching off into regular ducts, which divide and subdivide into such arboriform structures as the liver or pancreas, within the acini of which those other juices are elaborated, which are equally necessary to the final process. Around this mucous and secreting tissue, organic muscular fibres are found to arrange themselves, largely developed in some parts, and but scantily seen in others; while that, again, is surrounded by a cushion-work of areolar tissue, covered, when lying within the cavities of the body, with a delicate serous covering, called in the abdomen the peritoneum. Organs of such extent and complexity must necessarily be subject to manifold ailments, though for the sake of simplicity I shall consider them, as before, under the heads of nervous disorders, anæmic, or hyperæmic conditions, and degenerations.

The NERVOUS DISORDERS exhibit themselves in the forms of paralysis and spasm, of greater or lesser

degree, according to circumstances. Complete and permanent paralysis, (except in certain less important parts, such as the sphincter ani,) would undoubtedly soon lead to a fatal result; but a certain amount of torpor may frequently exist in one or all of these organs, which shall lead to much inconvenience, without positively inducing death. Thus, the stomach may become so inactive in its organic processes, that it shall cease to respond to ordinary stimulants, and so lose, in a great measure, its powers of appropriation. Torpidity of the liver is likewise a well-known condition, when the bile both diminishes in quantity and stagnates within the tubes of that gland. A similar condition of the intestines is exhibited in obstipation, the secretions and motions of these tubes being alike reduced from the standard of nature. Such conditions are obvious sources of primary dyspepsia or indigestion, words of very wide signification and varied meaning. When such internal torpidity is dependent on some affection of the brain, or other nervous centre, it is, of course, merely a symptom of that central lesion, and is to be treated accordingly. You will always observe, that in head-affections the bowels, &c., are exceedingly difficult of stimulation, and require an unusual amount of purgative medicines to produce any effect. And so it happens in epilepsy, insanity, and other such disorders, that the bowels are almost invariably constipated; and though, in such cases, it is very necessary that these passages should be cleared out, as a collateral means of treatment, the essential operations must be directed more immediately to the central source of disease. It is, however, to be also borne in mind, that prolonged irritation and chronic changes of structure in the mucous membrane may, and do, lead to irritation and chronic change within the cerebral or other grey centres; these, again, reacting on these mucous membranes, and the system generally, (as in hydrocephalus, &c.) so that at length a double series of morbid processes are found to be going forward, the priority of which it is often difficult to decide. The chief means of distinction will consist in this:—That, whereas, the central or essential torpor will have commenced suddenly or gradually, without pain, and unpreceded by diarrhoea, &c., the peripheral affection will have been ushered in by a considerable and prolonged manifestation of nausea, flatulence, diarrhoea, or dysentery, which may only disappear, and be replaced by torpidity, when the irritability shall be exhausted by the local disease, and the sensorium deadened by secondary effusions of fluid.

The usual causes of this torpor (apart from organic affections of the brain, &c.,) are, depressing passions, want of proper exercise, and the deprivation of nutrients of a sufficiently stimulating character, all of which causes operate in a high degree in civilised society; and hence so many sufferings in that state from indigestion, hypochondria, and a numerous train of similar evils. As to depressing passions, it is well known how great calamities will at once parch up the mouth, annihilate all desire for food, bind the bowels, and lock up the kidneys. Sedentary habits and a diet under par have equally obvious consequences; and the treatment,

therefore, must depend upon the leading circumstances of each individual case. If any organic affection of the brain be discoverable, that, of course must be managed as already described in the earlier lectures. The depressing passions which arise from any real causes can be modified only by the removal of such causes, or by the inculcation of that divine fortitude which enables us to meet the ills of life by equanimity, and even cheerfulness. Sedentary habits and improper diet at once suggest their own remedies; but in all such cases warm purgative medicines of a tonic kind are of the most essential service; and while, therefore, we enjoin activity of mind and body, with varied diet, we ought to unload the passages, and give them a first impulse by the use of such purgatives as aloes, aided by the bitter tonics of gentian or ipecacuanha, and such stimulants as ginger or capsicum. If the torpor be chiefly in the liver, it may require the special stimulus of small doses of mercury. When this treatment seems to have effected its object, it is not to be suddenly stopped (though patients are apt to do that of themselves), for that would be apt to reintroduce the torpidity, by the withdrawal of the accustomed artificial excitement; but the doses of the stimulants are to be gradually lessened, until it is found that the organs proceed in their work without requiring such aids. Such cases you witness in the physicians' room almost every day; and you will observe that I generally conclude the treatment, after employing smarter remedies, by the prescription of a single mild pill at night, containing two grains of carbonate of iron and one grain of aloes, ipecacuanha, and capsicum respectively. This, when the canal is brought to a tolerably healthy state, is quite sufficient to produce one full evacuation in the morning, without looseness; and that is exactly what ought to take place naturally. By all means let us avoid cold saline purgation; for that is always followed by an augmentation of the torpor, which the cobbling practitioner who employs it still seeks to remove by frequent and more frequent doses of his violent drug.

The opposite condition of excitability in the gastro-enteric nervous system leads to spasm, an affection already descanted upon, and familiar to you all as a dull or a sharp pain recurring at intervals, and relieved by heat and pressure. This most painful spastic action is commonly due to some degree of internal venous congestion, or to the presence of acrid foods or unhealthy juices or gases, especially the sulphurous, within the track of the canal. It is always of a reflex character, and has very frequently been experienced by most people in the stomach and bowels. When it occurs in the ducts of the liver it may produce jaundice, as is said. Some deny that such spasm ever does occur; but I see no reason why a spasm should not take place wherever there are muscular bands. True, you cannot prove it after death; but what of that, when so many clear proofs are seen of it during life? As to treatment, if acrid matters be present they must either be expelled or neutralised. To this end emetics and purgatives are our ready implements, along with

acids, alkalies, or alkaline earths, according to the suspected nature of the solid, fluid, or gaseous irritant. At the same time we must solicit the blood to the surface by heat, &c., and allay irritability by the employment of those sedatives which are emphatically known as antispasmodics. These indeed are to be employed alone when we see the spasms continue after the expulsion of all acrids, or going on without their presence, and merely from an excess of morbid functional irritability. Of all these remedies, the most powerful and immediate is, undoubtedly, opium, the doses of which must not be limited by the rules found in books, but graduated and continued according to the emergency. Opium, however, though excellent as an occasional remedy in acute attacks, is not to be habitually employed; for, when the stomach is chiefly affected, and in a chronic form, bismuth is chiefly to be depended upon; and when the bowels are troubled with such tormina, assafoetida, or garlic, or cayenne pepper, with flannels next to the skin of the abdomen, are to be mainly used. In simple spasms of an hepatic origin, opium and mercury will be found the chief means of relief, along with external heat. If hysterical, the ammoniated assafoetida or castor will prove of much value; and if the gastric spasm be of that atonic kind which ends in a fit of neutral vomiting, or water-brash, the best and surest means of relief I have usually found in opium and sulphuric acid; or, where these failed, opium and lead. Speaking of lead, you will, of course, understand that the pains which originate from the absorption of that metal, or from the conditions of dysentery or cholera, &c., are to be treated with specific views to those conditions, and not in the manner above described. As an illustration of the occasional peculiarities of such cases (for they are too common to require any illustration in general), I may remind you of a miserably dwarfed and shrunken young man, with an effeminate voice (an out-patient) who was treated for persistent vomitings and tormina, without any particular investigation, by all the usual means of calumba, laudanum, hydrocyanic acid, and the like, without any effect. At length, on instituting special inquiries as to the nature of the matter vomited, it appeared to be a pure oil, as it were, possibly uncombined choleic acid. He was accordingly told to stop all other medicines, and take a teaspoonful of carbonate of soda, and that alone, three times a day. From the first dose all vomiting and tormina ceased, and he was well for a considerable time. Persons of such habits of body, however, are always liable to a recurrence of their disorders.

HYPEREMIA of the digestive organs tends to the greatest degree of visceral derangement. It may either assume the arterial form, and so produce an acute or chronic inflammation, or it may be a passive venous stagnation, known as congestion. In all cases, and wherever situated, the inflammatory action may be distinguished from the congestive, by the greater amount of sharp pain under pressure, and the higher degree of constitutional excitement. This pain and excitement will be more or less according to the sensibility or vital importance of the organ which may be involved.

CONGESTION being the more common ailment, as witnessed in the every-day practice of the hospital, and being simple of treatment, may be at once disposed of. It may be present in the stomach, the liver, or the bowels, especially the lower great guts. The tongue, in such cases, is usually thickly furred, even after eating; a dark effusion is observed over the white of the eye, and a continuous dull headache is felt. The secretions will be deficient, and an obscure, heavy, sickening tenderness on deep pressure will be felt over that part of the track chiefly involved. If confined to the liver, that organ may be considerably enlarged, while it is sluggish in action, and if chiefly confined to the lower bowels; there may be swellings of the veins of the extremities or persistent piles. The indications are in any such case, to withdraw the stagnating fluid, and to promote circulation and secretion, and this is best effected by stimulant and free purgation. Where the condition is extreme, cupping or leeching may be required over the parts in the first instance; but, in most cases, a blue pill at night, with an aromatic and saline aperient in the morning, along with moderate diet and free exercise, will prove sufficiently effectual. These constitute the numerous class of cases in which those favourite remedies of Mr. Abernethy were found so useful. But the patients, in fact, need never have been ill had they lived with any degree of prudence, for it is heavy suppers, and made-up dishes, with rich pastry after a full meal of meat, and other unnecessary acts of eating and drinking, which lead to such maladies in nine instances out of ten.

INFLAMMATION is a more serious and urgent matter. Of such action in the gums, tongue, fauces, &c., where it is visible, and in which the treatment is familiar to you, I need not speak at all. Occurring in the stomach it is called gastritis, and, if acute, (which it very rarely is, except from irritant poisons,) you will have intolerable agony under the slightest touch, with vomiting of all ingesta, a red tongue, and profound prostration of the mental energies. In a less acute form, you will have all these same symptoms in a minor degree, but still tending to imminent danger, as the constitutional excitement is always great. The application of leeches over the organ is at once suggested by the circumstances, and these may be repeated, or followed by a blister, according to their effects. The coats of this organ are to be soothed at the same time by small effervescent draughts, containing hydrocyanic acid. Cold drinks, and even ice itself, may be employed with much benefit, and in some cases that resist the above treatment, a strong solution of nitrate of silver may be swallowed; but above all, care must be taken not to maintain irritation in the stomach by giving food. People will suppose, somehow or other, that no one can get through a severe illness without what they call support—support which, in reality is a burden. They cannot be made to see—except they be experienced—that it is better to retain one spoonful of beef-tea or gruel, than to reject fifty by straining and vomiting. But the management in this respect must be pointed out and enforced with the greatest emphasis, if you would succeed in the cure

of a very severe case. I never allow more than one teaspoonful of the mildest beef-tea or gruel at a time. And even when nourishment is required, it is surprising how much may be appropriated by giving that amount every quarter of an hour or so; whereas, more would be at once rejected. Gastritis of a more or less acute type, is always apt to arise in the course of any fever; but there is a fever very common in Birmingham, amongst young persons during the autumn, which seems simply symptomatic of a local epidemic gastritis. I should call it a gastro-enteric fever. It is ushered in by vomiting and epigastric tenderness, which are soon followed by the febrile symptoms. In my own practice I have invariably found that, if I was called in early enough, some leeches to the epigastrium and effervescent draughts would arrest all the expected train of symptoms; but when the disease had gained head, its natural tendency was to creep downwards through the intestinal canal, and to produce enteritis and dysentery, accompanied by a type of fever, becoming still more and more typhoid, and lasting for a month or six weeks. This may be viewed as the ordinary fever of this town, as contradistinguished from true typhus; a view in which I am confirmed by the prolonged local experience of Dr. Eccles and others.

HEPATITIS is not very common in the acute form; but when present, gives rise to a very depressant type of fever. The head is hot, the eyes are suffused, the tongue is furred brown, and the pain, accompanied with some turgidity, is very severe in the right side, where there is also felt a local increase of heat externally. In this form the peritoneal lining of the organ is generally involved, and the bile, at first diminished, is afterwards very acrid, and productive of profuse diarrhoea. The measures to be adopted, under such circumstances, are local abstraction of blood to commence with, and to be followed by a blister; then a continuous exhibition of blue pill or calomel, combined with hyoscyamus or conium, and alkalinized saline draughts. A very excellent illustration of the disease in this acute form, was afforded to us by the girl (I forget the name) recommended to the hospital as an out-patient by Mr. Ald. Phillips, the late Mayor. She had great difficulty in reaching the house, and on entering the room supported by her friend, looked exceedingly ill. The head was hot and the eyes were muddy and lustreless; the tongue had a deep brown fur; the cheeks were flushed; the whole body very hot; and the right shoulder inclined downwards towards the same side. Here was noticed some swelling, and the greatest amount of tenderness, whilst her general aspect was that of a person marked out for a long course of typhus fever. It was at once seen that she ought to be retained in the hospital, and she was accordingly taken to the low ward. Mr. Moore was requested to cup her over the liver, and then apply a blister, while she was placed at once under mercury and hyoscyamus, with frequent effervescent draughts. These steps were scarcely adopted before all the febrile and other symptoms began to abate; so that, ill as she was, she left the hospital quite well in about eight days. So beneficial

is it to meet an acute disease with prompt and decided measures. You are aware that such acute disease may lead to hepatic abscess either opening externally or into the digestive canal or cavity of the abdomen. One patient you lately saw with an abscess of this kind discharging its contents by the navel. Such a termination of acute or chronic action is to be sedulously guarded against.

Of the CHRONIC HEPATITIS, accompanied with duller tenderness, and sometimes great enlargement, we never had a better instance than in John Moore, of the top ward. His tongue, as in almost all such cases, was glassy, smooth, and clean, the complexion was sallow, the stools were variegated, and the liver—of deal board hardness—was felt extending over nearly the whole compass of the abdomen; but there were no dropsical effusions, as in most of our other cases. In all of them, but especially in Moore's—as the most marked in point of size and hardness—the iodide of potassium was found of great efficacy. Moore was cupped from time to time, used occasionally mercurial inunctions, took blue pill and colocynth at night, and iodide of potassium with conium, three times a day. The iodide had a very powerful effect upon him, and produced large pustular eruptions, which have permanently scarred his face. On this account it was obliged to be discontinued from time time; but, so conscious was he himself of the benefits of it to the liver disease, that he always desired a renewal of it. By these means his enormous and hard enlargement quite disappeared in the course of three months or so, when he became well and vigorous. Chronic hepatitis, however, will sometimes shrivel the proper structure of the liver, instead of enlarging it. The capsule of Glisson becomes hypertrophied, at the expense of the glandular parts, and we see the result in nutmeg liver.

Enteritis gives rise to a much more obscure pain than gastritis, and to a more smothered febrile action. It is generally accompanied by considerable cephalic heat; and is always recognised by pain under firm and deep pressure. In its largest acceptance it may involve not only the mucous and muscular coats of the intestines, but also the peritoneal lining; but, as the symptoms in the latter case are exceedingly altered and augmented, they have become grouped under the specific form of peritonitis, and, therefore, I shall not at present allude to any other than the affection of the mucous and submucous tissues. These, in this disease, are found to be in an inflamed condition; and when that condition extends to the larger bowels, we have all the symptoms of dysentery. In an ordinary case, this condition is to be subdued by the exhibition of mercury; while the motions of the bowels are to be stilled, and their sensibility subdued, by the conjunction of opium, or hyoscyamus, &c. Leeching or blistering may also be required over the abdomen, along with soothing emollients (such as decoction of poppy head, and hyoscyamus, &c.) The best form of mercury to be used, is the ordinary chalk preparation, and this may be advantageously combined with small doses of Dover's powder. You see us constantly adopting these reme-

dies in this rather common disease, which scarcely needs, therefore, any additional clinical illustration. If the complaint be very severe, as it may be, when arising from any sudden impression of intense cold, or in the course of a low fever, leading to specific inflammation at the ileo-cæcal valve, it may terminate in gangrene, or in perforation; in which events I know of nothing that can be done, except to use the means of perfect rest, and to leave the patient to nature. But I have never lost a patient under this disease, except it was accompanied by something more serious, such as carcinoma of the pylorus, as in the pedlar, Shay, and the poor old woman, Twells. Most commonly it is subdued by treatment, or ends in a weakening chronic dysentery, in which latter case it behoves us to use astringents, and to make the patient keep the recumbent posture. Additional doses of chalk may now be employed, in combination with catechu or logwood; mustard poultices to the abdomen will be useful, and where the slimy stools are frequent, or give rise to painful tenesmus, an opium suppository will be found valuable. When chalk and catechu will not serve the desired end, you have seen me employ, with marked results, acetate of lead and opium. The diet must also be attended to; so that it be simple and unirritating, and a drink of port wine and water will be advisable, if the body needs strengthening, which it generally does. Epidemic dysentery is often of a very low and fatal type, especially when attacking soldiers and the like in hot weather, who may be exposed to the damp chills of the night air and the open ground; but such a form scarcely ever occurs in comfortable towns, and, as already remarked, I have not met with any instance of death from it, except it has occurred as a terminal symptom of some more formidable disease, such as the carcinomatous cases above alluded to, or typhus, or phthisis in their latter stages. Let it never be trifled with, however, because it is, at all times, a serious matter. As in dysentery, we have mucous or mucosanguineous discharges; so in malignant cholera, or cholera asphyxia, we have a simple serous exudation. But that terrific malady shall be better discussed when we treat of blood diseases, for it is no mere affection of the bowels—very far from it.

When chronic affections of these parts have been much prolonged, they begin to give rise to many remote derangements, involving the lungs, the heart, the brain, the kidneys, and muscular and other systems generally; but more immediately they are apt to bring about a state of things which fits the body for the reception and retention of entozoa, such as the sarcina ventriculi, the round worm, the solitary worm, the hair worm, and the thread worm. These, in turn, give rise to very few positively local symptoms, except irregularity of appetite, and, perhaps some degree of griping. The body may waste, however, and become pale and generally irritable. The head will be hot and subject to a sense of giddiness. The nose and anus, or face and whole body, will itch, and the former may bleed or become sore. The patient will be disturbed in sleep, and grind his teeth. His eyes will sometimes ex-

perience a sudden momentary blindness. Dry cough will set in along with hiccup. Cardiac palpitation will frequently arise, and also fainting fits, or epilepsy itself, and other forms of convulsion will make their appearance. All these are traceable to the great law of reflex involuntary action, and are beautifully explanatory of the special arcs of sympathy that exist in the complex reticulations of the nervous system. I might well be tempted to dwell upon such things for a time, and indulge in some theories as to the reason why some parts sympathise more than others; but I should thus be wandering out of my straight line as a clinical physician, and shall, therefore, forego such arguments.

Through whatever curious channels of nervous intercommunication these effects are brought about, we have this simple and positive fact before us, that by the removal of the one exciting cause all the other evils are dispelled. You have had numerous instances of this result, both amongst out and in-patients. One in particular was the young girl Smith, aged 16. She had been subject to daily fits of epilepsy for a long period, and came into hospital labouring also under a great degree of anæmia. Turpentine was administered, and Mr. Moore observed that there had passed a round worm, eight inches long and proportionately thick. After that she never had another fit, and a course of iron restored her afterwards to perfect health. She left the hospital in one month a plump and well-coloured girl. There can be no question of the value of the turpentine in most cases of vermination; but it will sometimes fail, and is also a rough remedy. But you have often seen me employ, with good effect, the oxide of silver. Sometimes in these cases the worm or worms pass; in others they are never seen; but, at the same time, all the associated symptoms disappear, and we, therefore, infer their death or their temporary prostration. Sulphate of zinc will also act after this manner; and the koussou, as you all know, has lately been much celebrated. Oil of male fern I have lately used a good deal, but with no very marked effects; and as to the pomegranate, I cannot pass any judgment upon it. Next to the koussou, so objectionable in point of expense, I am clearly favourable to the turpentine; powerful and rough though the dose may be.

The DEGENERATIONS of structure which occur in these parts will be spoken of at length when we come to treat of diseases of the blood, &c. For the present I may merely briefly allude to some of those changes which are most common, in order that our general review of those morbid derangements may be complete. In the first place, there are certain formations of a fibrous or scirrhous character, which occur at particular points where some long-continued irritation has existed, combined with frequent and, perhaps, severe pressure. Not that we are always able to trace these causes in each instance; but, from the irritation being evidently dependent in some cases upon the presence of pins, fish bones, or other foreign irritants, we are led to the general inference. In the œsophagus, and at the pylorus and the rectum, we most frequently meet with those simple indurated swellings. The first is to be

suspected from difficulty of swallowing, and the last from constipation and the narrowing of the stools. In the pylorus the chief symptoms are, pain, with vomiting some time after taking food, and, if the swelling be of any magnitude or hardness it will be felt outside, under diligent manipulation. These swellings may gradually assume a more and more scirrhous character, by the condensation of their fibrous structure, and afterwards, according to the number of soft cancer-cells which may intervene between these harder fibres, or the rapidity of their deposit and destruction, the mass may become, in a greater or lesser degree, a regular phagedenic carcinoma. In the earlier stage of simple induration, the bougie may be employed with great success, both to the œsophagus and rectum. The affection at the pylorus is more to be controlled by very soothing treatment—namely, the use of bismuth and conium, and food of the most digestible and unstimulating kind, with blisters to the epigastrium. Induration of the liver is a much more hopeless disease than the hepatic enlargement already spoken of. We can, in fact, do nothing beyond attempting to check its further progress. In such a case the organ is shrunken, and hardened at the same time. The fibrous skeleton or framework, called the capsule of Glisson has, in these circumstances, become thickened and hardened, and has so pressed upon the nutrition of the true glandular structure, that that has been destroyed and absorbed, and of course can never be renewed. Besides this, however, there are sometimes found in the liver large cartilaginous tubers, which in due season assume the features of cancer, as was witnessed in the body of the old woman Twells. Of the fatty degeneration that so often occurs in this organ, and which you have the means of seeing so very frequently, especially as accompanying the latter stages of phthisis and other exhausting diseases, I shall say nothing at present, but leave its consideration to another part of the course.

When carcinomatous action has set in, the disease is to be inferred partly from constitutional and partly from local symptoms. There is, in almost all cases, great emaciation, and a peculiar straw colour, or dirty white hue, pervading the countenance. Agonizing lancinating pains will also most likely exist, greatly aggravated by pressure; and the tumour may likewise be felt through the parietes of the abdomen, if in a situation where it is possible to be so examined. The mass, as you recollect, was very distinctly felt indeed in the patient Twells, though it occasionally disappeared. In the pedlar, Shay, it was more difficult of recognition, as it seemed to recede from pressure, but, on suddenly, though gently, keeping my finger down, I felt it, as you are aware, sufficiently distinctly and often, as to give, taking other evidences into consideration, a decided diagnosis of the case.

Twells had been a washerwoman, and had been subjected to pressure there from the tub. No doubt, also, she would take frequent drams of pure gin, as is the custom of such people. Shay was an inveterate drinker of raw rum, often upon a completely empty stomach. In both of these cases large indurated masses were

found at the pylorus, composed of fibrous stricæ, which cut like cartilage; while the surface was a white pul-taceous milky structure, traversed by large veins, and margined by an inflammatory blush. Twells' liver, likewise contained several hard tubers of various size, from that of a very large walnut, down to a pea, which cut like gristle, and contained milky matter in their centres. Relief was afforded in these cases by leeching, bismuth, and conium, and also by hydrocyanic acid and opium. All this, however, was merely palliative, and they both ultimately died of starvation, being reduced to skin and bone.

ON UTERINE HÆMORRHAGE.

By GEORGE KING, Esq.,

SURGEON ACCOUCHEUR TO THE DORCAS SOCIETY, BATH.

In a recent number of the *Journal* there was an article "On Uterine Hæmorrhage," by Mr. Nowham of Farnham. As uterine hæmorrhage is a subject of vital importance to the obstetric practitioner, and whether it takes place during gestation or parturition, it is one of the most frightful and perplexing circumstances that could occur to the medical attendant, any information on such a subject must be useful; and Mr. Newnham's forty years' experience must give weight and interest to his observations and practical remarks, although there may be nothing very peculiar in the cases, or new in the treatment. The publishing them may encourage and give confidence to, if not instruct, the young practitioner, if he should be so unfortunate as to meet with one in his practice. Practical information is much more likely to impress the mind than theoretical. Many professors become teachers before they have hardly become practitioners. The object of this paper is to direct the attention of the readers of the *Journal* to internal uterine hæmorrhage, and to bring before their notice a few cases that have recently occurred in my own practice. This passive or insidious hæmorrhage going on within the cavity of the uterus, whether during pregnancy, at the time of labour, or after the contents of the uterus were expelled, does not seem to have attracted that notice in the practice of midwifery that its importance deserves. That distinguished obstetric physician, Dr. Baudelocque, (whose death was noticed in a late number of the *Journal*), some years since published a pamphlet, entitled "*Traité des Hæmorrhagies Internes de l'Uterus*," and the cases related by him of concealed hæmorrhage are highly interesting and well worth consulting. I have not met with any other work entirely on the subject. In internal hæmorrhage we do not meet with those frightful appearances or terrific floodings,—gushing out the vital fluid until stopped by syncope, or nature refuses to supply more—and in this alarming condition it is well known that there is no time for reflection, consideration, or consultation; all our skill and moral courage is at once suddenly taxed, and we must instantly

act. Still internal uterine hæmorrhage is equally dangerous, requiring all our attention and the most prompt and energetic treatment; and although it may proceed slowly and unobserved, its effects are, nevertheless, often fatal to mother and child, the latter generally. There may be no external sign of the mischief going on, and its effects on the constitution are not known until repeated faintings take place, the patient becomes exhausted, and the pulse almost extinct. For these distressing and troublesome cases our remedies are but few, and our controlling means very limited. Dr. Blundell remarks in one of his lectures on this subject:—"That it is of rare occurrence, and in the present condition of our knowledge scarcely admits of a remedy." This statement was made some years since, but I do not know that there has been any improvement in this branch of our practice. The use of bandages and pressure, I believe, is more practiced now than it was at the time the Doctor's lectures were published, but I have yet to learn the good they are to do. I believe in internal hæmorrhage this kind of treatment does more harm than good. The following mode of applying pressure for the purpose of stopping internal uterine hæmorrhage was recommended by the late Professor Davies:—"To roll a pillow into a hard pad, then place it on the abdomen of the patient, and sit upon it." The learned Professor has omitted to tell us how many stone the sitter should weigh. This is very important, as all medical men are not the same size and weight. He was himself rather weighty.

The following plan of applying pressure in cases of internal or external hæmorrhage is recommended in a recent volume of the *Lancet*:—"The accoucheur is directed to take three or four octavo volumes, and wrap them up together in a towel, then lay them longitudinally over the rectus muscle, and place a half-hundred weight upon them." Should there be any blood left in the uterus or pelvis, when these weighty measures are applied, this certainly is a good way of pressing it out, and not unlikely to extinguish life too. While all this preparation is going on, or as the patient sinks, no doubt the flooding stops. I believe a bandage is a great support to the muscles of the abdomen after labour, and is no doubt a great comfort to the patient, and it will also tend to keep down the uterus within the pelvic cavity, but my opinion is that it has but little effect in restraining or stopping the discharge. Pressure by the hand in order to secure the contraction of the uterus immediately after the delivery, is very useful, and should be done.

The only medical remedies that I know of are tincture of opium and the *Œcale cornutum*; and mild aperients should be occasionally given, to keep the intestinal canal emptied, to prevent any irritation of the uterus from that quarter. Cold water is also a most valuable remedy in all cases of uterine hæmorrhage. If internal uterine hæmorrhage should occur at an early period of pregnancy—say within the second and third month—it may be restrained by tincture of opium, the recumbent position, and rest of the mind as well as of the body. At a later period, I fear, nothing but the removal of

the contents of the uterus—no other treatment can be depended upon—will stop it; and this should be done early, before the system becomes affected by the great loss of blood. This operation is, like many others, often delayed too long. Nothing is to be gained in these cases by waiting, as, in all cases, we may be pretty sure the child is dead; and the mother may follow, if we are not very prompt and active in our movements. The only means available, that I am aware of, for removing the contents of the uterus at this period of gestation is a small hand and the blunt hook. In the last month or during parturition, ergot is the only medicine to be relied on. This is a powerful auxiliary to the uterine pains; but I have noticed that it does not seem to act on the uterus until the liquor amnii, or part of it, is discharged, and I do not expect it would have any influence on an uterus distended by internal hæmorrhage. The *secale cornutum* seems only to be capable of stimulating the action of the uterus, not exciting it. When the expulsive power of the uterus has been set in motion from natural causes the ergot possesses the peculiar property of helping it. The last and most frightful, as well as troublesome to the accoucheur and dangerous to the patient, is internal uterine hæmorrhage after delivery. The only contracting power in this case is cold water. This produces contraction of the mouth of the blood vessels that are open, pouring out their contents into the cavity of the uterus. The sudden application of this simple but most valuable remedy, and the shock to the system produced by it, is no doubt the cause of hæmorrhage ceasing; but much of the efficiency of this powerful agent in these urgent cases is in the mode of applying it. It is not enough to put up a cold napkin in the usual manner, wet with water that has lain a long time in the bed-room. The water should be procured immediately from the pump or spring, and the napkins saturated with this, and *spread* over the pubes and the whole hypogastric region, and removed and *fresh* ones applied every *two* minutes, till we are sure the hæmorrhage is checked. The repeated shocks produced by this rapid removal of the napkin produce the most salutary effects in these perplexing cases; and while we are trying or looking for more complicated remedies the patient may go off in a fatal syncope. The following cases which I have lately met with—and it is singular that they all occurred within a few days of each other—will, I think, illustrate and explain some of the circumstances connected with internal uterine hæmorrhage:—

Case 1.—On Saturday morning, September 21st, about four o'clock, I was called up to Mrs. H., who had engaged me to attend her with her first child. On my arrival she said she was got better, and I was not wanted. I found that she had been roused from her sleep by a flooding, which greatly alarmed her; but she was in no pain. She had arrived at the full period of gestation. I satisfied myself that the discharge had stopped, ordered her an anodyne draught, and left her, with directions that I was to be sent for if the flooding should return before I called. At twelve o'clock I saw

her again. There had been no return of the discharge; but the nurse told me her mistress was “rather queerish,” and she thought I should soon be wanted. About three o'clock P.M. I was sent for in a hurry, and found the pains coming on regularly, but she seemed unusually faint and weak. On examination, I found the os uteri dilating, about the size of a crown piece, and the head presenting. With the next pain I ruptured the membranes. There was not a great deal of water (*liquor amnii*) discharged. In about two hours after a very fine dead child was born. From its appearance I should say it had not been dead long, as it was exsanguineous and flabby, clearly proving that it had suffered from the hæmorrhage, although the mother was a strong robust young woman. She was very faint for some time after the delivery. There was not the slightest hæmorrhage during the labour. The placenta was expelled without any assistance on my part, about five minutes after the child; but before it was a large, tough, coagulated mass, as big as the child's head, the produce, no doubt, of the insidious internal hæmorrhage. The patient had but little discharge afterwards, and did well.

Case 2.—The same evening, about eight o'clock, I was requested to call on Mrs. R., who was in the eighth month with her first child. She had been out to tea, and on her return home she felt herself sick, and thought that the green tea which she had drank did not agree with her. She retired to her bedroom; and in the act of throwing up her tea, the waters broke, and rather a large quantity was discharged, with slight pain in the back. For these pains in the back I had been consulted some days before; but I did not prescribe for them. On examination, I found no signs of labour. The uterus was very high up and difficult to get at. The os uteri was not at all dilated. She was frightened and restless. I gave her twenty-five drops of tincture of opium. About twelve o'clock she became more tranquil, and I left her. At five o'clock in the morning I was called up. On my arrival the child was born. It was very small, and quite blanched. There did not appear to be a drop of blood in it. On dividing the head not a drop escaped. I had some difficulty with the afterbirth. Before it came away I had to remove from the vagina a hard black mass, which turned out to be layers of coagulated blood, which I have no doubt had been accumulating from the first time I was consulted about the pains in the back. This patient also got about very well, with the exception of the milk being rather troublesome. It is very clear that in both these cases the internal hæmorrhage was fatal to the child; and from the exsanguineous appearance of the bodies, it must have been from the placenta, and not from the vessels of the uterus, perhaps towards the insertion of the cord into the placenta. Had I ruptured the membranes at my first visit, in the first case, the child might, I believe, have been saved, as the effusion appeared to be recent; but there was then no symptom to demand such treatment; and it would, I think, have been considered bad practice.

Case 3.—The next case is one of a different character. On Sunday, October 4th, at five o'clock p.m., I was requested to see Mrs. B. immediately, who was in labour. She had recently come to reside in the neighbourhood, and had not engaged a medical man. I followed her husband. On entering the room I found three women standing by the bedside, looking at a woman on the bed that appeared to me to be in the last stage of phthisis, as she had a little hacking cough; she was too weak to give any account of herself. The mother informed me that she was very young, but she had got four children and that she was six months gone with the fifth, and in the morning, between six and seven o'clock, a flooding had come on, and had continued a little ever since, but it did not alarm them, as there was no pain till about two hours ago, when she became faint, and they had not been able to keep life in her. I placed my hand over her abdomen, and found it greatly distended. I then made an examination per vaginam; there was no blood in the passage; the neck of the uterus was low down in the pelvis; the os uteri slightly dilated and very thin. I ruptured the membranes. This seemed to rouse the patient, and the uterus immediately began to contract, and the pains became very rapid, and in half an hour the child was born, but the size of the uterus was not much lessened; it had receded and was as buoyant as a balloon. By steady pressure by the hand, I got it down, and by this pressure the placenta was expelled without any other assistance, and with it an immense mass of coagulated blood, something the shape of the placenta, and quite as large. The woman, as might be expected, was frightfully exhausted, but by the kind care and attention of those about her, she is getting about without much medical treatment. There can be no doubt that this hæmorrhage proceeded from the vessels of the uterus itself, and it is the kind of internal uterine hæmorrhage that often proves fatal to the mother.

Bath, October 21, 1851.

Hospital Reports.

CUMBERLAND INFIRMARY, CARLISLE.

CASES

Reported under the Terms proposed by the Association.

By CHIRURGS.

Case of Hydrophobia treated by Chloroform.

THERE is, perhaps, scarcely any disease to which the human frame is subject, more deserving of and more needing patient investigation and earnest inquiry, than hydrophobia; the peculiar nature of its symptoms, its rapid course, its uniformly fatal result, the inconstancy of the morbid appearances which attend it, are points in its history which are calculated immediately to chain the attention of all. Notwithstanding the diligent

investigation which able and distinguished men have at different times bestowed upon it, we are still completely in the dark as to its true pathology; almost all known remedies have signally failed in effecting a cure, and until the advance of physiological science shall have greatly extended our means of pathological research, we can only hope by empirically trying new remedies to have the good fortune to meet with one, if such there be, which may have the power of arresting the progress of this dreadful disease. Such being the case, it becomes a matter of great moment that every unsuccessful application of a new remedy should be immediately and faithfully recorded, that future experimenters may not waste valuable time in trying substances, the inefficiency of which has been already fairly proved. It is a feeling such as this which induces me to lay before the profession the following case, in which, I think, I may confidently assert, that the effect of chloroform, (which from its power of relaxing muscular spasm, carries with it a *primâ facie* prospect of success), has been fairly put to the test. I shall reserve what observations I have to make upon the subject until I have detailed the circumstances of the case.

John James Graham, an intelligent healthy boy, aged three years and three months, was bitten on the 29th of January last by a dog, supposed to be rabid; at the time the accident happened, the child was playing with a companion in the road, in front of its own home; the dog flew at them, bit them both severely, and worried them. Upon examination of the little patient, it was ascertained that the apex of the nose was nearly detached; that there were three severe and extensive wounds on the side of the face, situated one beneath the other, one of which extended completely through the cheek into the mouth; that there was a deep wound beneath the right ear, laying bare and lacerating the masseter muscle; that the tragus of the same ear was also injured, and there was a deep punctured wound of the back of the right hand, besides some other abrasions of less moment. The extent of the injuries on the side of the head was such, that it was deemed impracticable to resort to excision, or the application of any cauterizing substance, as by so doing, the greater part of the side of the face must have been removed; long continued ablation, kept up for two or three hours, was therefore alone depended on; the lips of the wounds were brought together with strapping, and ordinary dressings applied, about five hours after the injuries had been inflicted; the same treatment was also adopted for the wound on the hand. The sores progressed well and rapidly, and the patient was discharged on the 11th of February, with all of them nearly healed. On the afternoon of Friday, Feb. 20th, the twenty-second day after the receipt of the injury, his mother first remarked that he did not appear in as good health as usual, his appetite was diminished, he became exceedingly restless, and was frequently observed to draw a deep sobbing breath; he spoke repeatedly of the dog which had bitten him, apparently with great perturbation; he slept badly that night, and the next morning became more fidgetty, feverish, and anxious-looking. His bowels

being rather confined, and his tongue furred, his mother gave him some infusion of senna, which she had some difficulty in getting him to swallow. During a great part of the day he suffered from vomiting, recurring hourly. Saturday night his rest was even more disturbed than it had been the night previously, and on Sunday he gradually grew worse and worse. His mother gave him a purgative powder which she had obtained from a chemist, after this his bowels were freely opened, and they subsequently continued regular. Towards the evening the restlessness increased, he became very excitable and nervous, and remained awake, in the same condition, during the whole night. The symptoms now began to be more pronounced, the slightest movement annoyed him, and produced a sort of convulsion; he frequently started, as though frightened, and clung to those around him, hiding his head with manifest alarm. On Monday morning he was attacked with a more severe convulsion than he had had previously, and his mother reports that he attempted to bite those around him; this first led her to fear the real nature of the malady, and Mr. Page was sent for. He found that the child had the greatest difficulty in swallowing fluids; he could only be prevailed upon to attempt to take any by means of a teaspoon, which he guided to his mouth with his own hands, and each effort at deglutition was attended with a spasmodic gasping, and a sort of convulsive condition. At Mr. Page's recommendation, he was immediately brought to the Infirmary, into which he was admitted at about 12 o'clock, A.M., Monday, February 23rd. Soon after his arrival, he was offered some warm milk and water, his mother remarking that he always swallowed cold fluids with greater difficulty. After many ineffectual attempts, (during which he took up the spoon, but before he could convey it to his mouth, turned away with a convulsive shudder, and a peculiarly depending expression,) he succeeded in swallowing a small quantity, without much apparent difficulty; after the first two or three mouthfuls, however, each attempt produced a convulsive gasp, and was made in a hurried alarmed manner. He was at this period, as he had been throughout his illness, perfectly sensible and conscious, his tongue clean and moist, his skin moderately perspiring; he complained of no pain in any part of his body, and the cicatrices of the sores, which had all completely healed, were looking healthy, and presented no unusual appearance; his eyes, at times, had a somewhat wandering aspect, his pupils were much dilated; he frequently started, as though frightened; his manner was extraordinarily anxious and excitable, he seemed totally unable to keep himself quiet, and there was a peculiarly hurried character about all his actions, which it was impossible to describe. In the course of the afternoon, the symptoms slightly diminished, he was able occasionally to take a few teaspoonfuls of broth and tea, and he also contrived to eat an egg, but towards nine, P.M., they recurred to as great, and greater an extent than previously, and Mr. Page determined to try the effect of chloroform, it was therefore immediately administered, and its action kept up for an hour; on allowing its

influence to subside, the symptoms returned, and it was evident the progress of the disease was unchecked, he was even more restless than formerly, and although at his own request some tea was offered him, he was totally unable to swallow it, or even to bring the spoon to his mouth, the effort to do so throwing him into a convulsion, his eyes almost starting from his head, and the spoon grasped firmly by both hands, being held out at arm's length before him. At eleven o'clock, the administration of the chloroform was resumed, and continued, with but little intermission, for eight hours. Whilst under its influence he remained perfectly quiet, breathing moderately, with his pulse full and regular, though rapid, 120 and upwards; on allowing its effects to pass off, however, even in a slight degree, violent spasmodic action of the muscles of the throat ensued, and laboured respiration, apparently from the accumulation of tenacious mucus in the air passages. At seven, A.M., on Tuesday morning, the administration of the anæsthetic was suspended; the child soon recovered consciousness, but was unable to articulate; each act of inspiration was attended with a convulsive spasm of the muscles of the throat, including the sterno-mastoidei, and an extensively diffused mucous rattle; his countenance, from having been quiet and motionless, soon became anxious and troubled, he struggled and gasped for breath, his limbs were disturbed by convulsive starts, the teeth ground against each other at each inspiration, through spasm of the muscles of mastication, a quantity of tenacious mucus accumulated about the mouth and air passages, occasioning great uneasiness, and increased difficulty of respiration, and he died at length, thirty-five minutes after the chloroform had been laid aside.

It is to be regretted that a proper examination of the body could not be obtained; it was with the greatest reluctance that permission was even granted to examine the brain, which was found altogether in a normal condition, and presenting no evidence of inflammation, either local or general.

It does not consist with my present purpose to enter into any lengthened consideration of the many interesting points which this subject embraces, but I cannot refrain from making some remarks, which the circumstances of the above case suggest. I need scarcely observe, that it affords a manifest proof of the absurdity of the opinion, which has been maintained, even by sensible men, that no such disease as hydrophobia exists; that the many cases which have been, at different times, reported, were purely cases of a highly-excited imagination, acting upon nervous and irritable subjects. No one surely will be bold enough to attribute the symptoms, in the present instance, to such a cause; apart from all other arguments, the age of the child must, I think, convey to the unprejudiced mind, a conviction of the reality of the affection. I am induced, however, to allude to this erroneous notion, on account of the injurious influence which it exerts, especially when emanating from professional men, upon society at large, and its tendency to lull into dangerous security those who have been bitten by a rabid animal, and are thus

open to the danger of becoming the victims of this terrible disorder.

Another interesting question which arises is, as to the propriety of performing excision when the extent of surface implicated is very great, and the tissues and parts affected important. When we consider that but a comparatively small number of the persons bitten by a mad dog are ever affected with this disease, it becomes a delicate question to determine whether, when the original wounds are themselves extensive and severe, we are justified in subjecting a patient to what must be then looked upon as a *very* serious operation, to ward off a calamity which *may* never occur. However, on the other hand, we must bear in mind, that over the disease itself we have no control, should it supervene; the patient will inevitably die. And we should also remember, that the only efficacious means of prevention we possess, are excision and free cauterization.

As to the abstract propriety of resorting to excision in the treatment of wounds inflicted by a rabid animal, but little difference of opinion exists, I imagine, amongst the members of the medical profession; still cases must, and no doubt often do occur, in which it becomes exceedingly difficult, and even dangerous, to carry this principle into practice. A humane surgeon will naturally, and very properly, shrink from carrying the mutilation of a fellow-creature's person beyond what the stern rules of necessity imperatively demand. For my own part, however, my horror of hydrophobia is such that I should feel inclined to stretch surgical interference to its furthest limit; and I would especially resort to excision, if by any means practicable, in cases where the bites had been received on exposed surfaces, as the hands and face, because there would then be no probability that the saliva, which is now pretty generally acknowledged to be the seat of the poison, could have been previously removed from the animal's teeth at the time of inflicting the injury, which circumstance *might*, and no doubt often *does*, take place, when persons are bitten through their clothes.

It is worthy of observation, that the administration of chloroform, though I believe it must entirely be thrown aside as a curative agent, does afford manifest relief to the patient's sufferings. There cannot any longer be a question but that it fails to exercise the slightest influence on the progress of the disease. Its course remains as rapid and uniform, and its termination as certain. Should all other means, however, fail, it will ever undoubtedly be a matter of rejoicing to medical men, that they still have it in their power to mitigate, in some degree, the heart-rending sufferings which the miserable victims of this fearful malady are fated to endure. It is scarcely necessary for me to observe, that great care is required in the administration of the anæsthetic; the action kept up must be moderate, and but just sufficient to maintain the patient in a state of tranquillity. If properly managed, experience has fully proved that there is not the slightest danger attending the inhalation of the vapour, it is only requisite that the respiration and the pulse should be carefully attended

to, and as long as they continue unaffected no danger need be apprehended.

I will only further remark, that there is yet one method of treatment left untried, I allude to the employment of the wourali poison, artificial respiration being maintained until the effects of the preparation have passed away. The use of this material was long ago proposed by the gentleman whose indomitable energy and perseverance has alone obtained it, Charles Waterton, Esq., of Walton Hall, Yorkshire; he has never yet, however, had an opportunity of putting his proposal to the test. His interesting experiments upon animals, which were published in the *British and Foreign Medical Review* of 1839, are well known to the profession, and it is worthy of remark that it is there mentioned, that this treatment was resorted to, with success, upon a horse affected with tetanus, a disease in some degree allied to the one at present under consideration. Many, no doubt, would object to this plan of treatment, on account of the risks which must necessarily be incurred, the experiment of restoring animation by artificial respiration, under such circumstances, never yet having been tried upon the human frame, but when we have to attempt to combat the effects of so frightful a disease, which is acknowledged to be incurable, I believe we are justified in resorting to any means which afford *some* rational prospect of success, even though there be much attendant danger.

LEICESTER INFIRMARY.

CASES

Reported under the terms proposed by the Association.

By DR. JOHN BARCLAY.

Case of Internal Strangulation of the Small Intestine; Recovery.

JOHN PALMER, aged 24, shoemaker, residing in Leicester, married, bilious temperament, and highly hypochondriacal. Has suffered previously from dyspepsia and diarrhoea. Admitted as of emergency November 13th. He states that he was at the theatre on the 10th instant, and was crushed while leaning with the upper part of the abdomen on the front rail of the gallery for about twenty minutes, when he felt sick and went out and vomited, and has had no stool since. On the 11th there was pain about the head of the colon. Simple purgatives were administered; and on the 12th ten leeches were applied to the chest.

November 12th, A.M.—Face anxious; much depressed; pulse rapid; anorexia; tongue foul and moist; no stool for three days; urine scanty, not high coloured; only general uneasiness in the abdomen.—R. Hydrarg. Chlor., gr. x.; Pulv. Opii., gr. ij. Statim. injiciat enema terebinth. App. abdom. emp. sinap.

Half-past 10 P.M.—Was sick after the powder, and several times during the day. Injection returned

untinged.—R. Acid. Hydrocy., m. ij.; Aq., oz. iss.—
R. Hydrarg. Chlor., gr. ij.; Pulv. Opii., gr. ss.

14th, 7 A.M.—No relief.—R. Hydrarg. Chlor., gr. v.;
Aloet., gr. ij. This was immediately rejected.

11 A.M.—Tongue brown and dry; much thirst;
pulse 120; Abdomen full, not tense, and soft; a little
pain on deep pressure, about four inches to the right of
the umbilicus; vomiting recurring about every half hour,
and has now a stercoraceous odour. To have a warm
bath, 98°, and remain in it till faint, and then a large
terebinth enema, and twelve leeches to the painful spot.

10 P.M.—The surgeon reported that there was no
hernia. The pain removed by the leeches. The warm
bath produced faintness; but the glyster returned with
no trace of faecal matter. Urine sufficient and natural.

15th, 11 A.M.—A restless night; constant vomiting
of stercoraceous fluid. To have an injection of as
much warm water as can possibly be thrown up.

Half-past 10 P.M.—Nearly a gallon of warm water
has been twice thrown up into the bowels. It was so
long retained that it was deemed advisable to try to
stimulate the intestines to act by—R. Ol. Croc., gtt. ij.,
in a pill.

16th, 11 A.M.—The croton oil was vomited, and
there has been no stool; tongue brown and moist;
much restlessness; a little delirium; abdomen rather
tympanitic, but no pain anywhere on pressure.—R.
Ol. Tereb., dr. vj.; Creasoti, gtt. ij. Fiat haust
statim sumend. A turpentine stupe to the abdomen.

10 P.M.—No relief. The draught was rejected.
The stercoraceous vomiting occurs at intervals of a few
minutes. Pulse 120, and feeble. Urine natural.

17th, half-past 10 A.M.—Rested badly, vomiting
most of the night; the pulse quick, and not so
feeble; not much distension, but a little pain to the
left of the umbilicus. To have an injection of two
pints of warm olive oil. The practicability of an
operation having been suggested by his friends, and
strongly urged by himself, it became the subject of
conversation with my colleagues, and a consultation
was held in the afternoon. This I was, unfortunately,
unable to attend; but it was unanimously decided not
to entertain the idea, chiefly on account of the failing
of the pulse and state of collapse, which the thought
of an operation and the removal to another ward had
combined to produce. It was also decided that the use
of tobacco was contraindicated.

17th, 11 P.M.—Much worse; pulse 100, and feeble;
vomiting horribly offensive; and hiccough set in, which
was very distressing. Inclined to be drowsy. Two
grains of opium to be given if necessary.

18th, 10 A.M.—Has slept a little without the opium,
otherwise *in statu quo*. Hiccough and vomiting con-
tinue; urine natural. The pulse so much stronger,
and the abdomen, though full, so soft and free from
pain, that another consultation of all the medical
officers was called at half-past two P.M.

Half-past 2 P.M.—At that hour we found him
suffering dreadfully from the hiccough and vomiting,
the latter to the amount of a quart at a time, of thin
faecal matter; skin cold; pulse 100, feeble. The abdo-

men still soft, and no pain or uneasiness anywhere on
pressure. The total want of any guide to the seat of
the strangulation, the possibility of their being a hernia
through the diaphragm, and the extreme hazard of the
only operation which could have been attempted, viz.,
to open the abdomen to the extent of three inches,
about the head of the colon, and pass the whole of the
small intestines through the fingers, and the failing feeble
pulse and cold skin, led to the unanimous resolution
that no operation was justifiable, however much urged
by the patient himself. He was considered to be sink-
ing, and my surgical colleague and myself went to his
bed-side to communicate the sad intelligence to him—
that there was no hope of his recovery. Just at that
moment the nurse heard a gurgle, threw down the
bed-clothes, and found that a small quantity of liquid
faeces had passed. He was then ordered Tinct. Opii,
m. x., every hour, on a little sugar, and an enema, with
Chloric. Ether, dr. iss., immediately.

11 P.M.—Very quiet. The vomiting continued till
six P.M., everything being immediately rejected. Since
then quieter; skin hot; pulse 100, stronger; abdomen
soft. Two stools after the injection, which were care-
fully examined, and contained no membrane of any kind.
Omit. omnia.

19th, 10 A.M.—Better; pulse 96, stronger; hiccough
still distressing; another stool, liquid, and containing
no membrane, this morning. R. Acid. Hydroc., m. ij.,
Aq. oz. j., singulis horis; and a blister to be raised
over the stomach with the acetum cantharidis.

4 P.M.—Going on well. The hiccough stopped as
soon as the blister rose. Omit. haust.

20th.—Going on well; tongue still dry. R. Ol.
Ricini, oz. ss.; Tinct. Opii, m., v., statim. This acted
well. On the 23rd he had a formed stool, and on the
30th he was discharged cured.

REMARKS.—The desire to save a fellow-creature
from what seemed inevitable destruction by a most
horrible death, caused me to entertain the idea of an
operation when urged by the patient himself. The
result, so unexpected—so happy, only teaches us how
unlimited are Nature's own resources, and the case
leads me to the conclusion that interference by art can
hardly be justified, under any circumstances, before
peritonitis has set in, where there is a chance of relief,
as in this instance, almost at the last hour, when every
hope was relinquished, while after inflammation of the
peritoneum has commenced, probably no one would
think of suggesting any operation.

Provincial Medical & Surgical Journal.

WEDNESDAY, MARCH 31, 1852.

AN action at law has recently taken place at
Wolverhampton, which distinctly settles the
question as to the supposed impunity with
which some nefarious traders palm off their

nostrums under the guise of prescriptions by eminent members of the faculty.

The action alluded to (BAKER *v.* LANGMAN) was laid for the recovery of two shillings and ninepence, which was the sum paid for a box of pills, purporting to be "Concentrated Cod-liver Oil" Pills, prepared under the direction of Sir J. Murray," but which were neither the prescription of that physician, nor did they contain a drop of the oil referred to. The plaintiff being deceived by this impudent forgery soon sought reparation for the fraud which had been practised upon him. Sir JAMES MURRAY himself appeared as a witness, and indignantly repudiated any connection with the nostrum, the result being that the defendant had an adverse verdict returned with costs.

Sir JAMES MURRAY deserves the esteem of the profession for the manly way in which he has vindicated not only his own reputation, but, *pro tanto*, the character of the profession at large; and for having the courage, while the result was still uncertain, to show that the name of a medical practitioner cannot, with impunity, be hawked about by any druggist or quack who may venture upon the forged authority of a distinguished name, to play upon the credulity of a physic-loving public. The decision is as important as it is just, and will, we trust, stimulate others whose names are similarly desecrated to ensure their disconnection from the "pills," "lozenges," and "wafers," which are to be met with in the columns of every newspaper. Hitherto some excuse has been found in the uncertainty of the issue, for the apparent apathy with which this disgraceful appropriation of their names has been regarded by men who may justly feel proud of their high professional position; but the way being now made clear, we may reasonably look for similar actions in other quarters, a few of which will effectually put a stop to a crying evil.

Reviews.

On the Natural History, Physiological Actions, and Therapeutical Uses of Colchicum Autumnale, &c.
By J. M'GRIGOR MACLAGAN, M.D., Edin. Edinburgh: Sutherland and Knox. 1852.

FROM the importance of colchicum in the several affections depending upon the gouty and rheumatic diathesis, and the very indefinite notions

which prevail respecting its *modus operandi*, in the former disease more particularly, not only among the public, but among professional men also, a truly scientific investigation like the present must be considered an acceptable addition to pharmacological literature. Without following the author too closely in the separate steps of his inquiry, we may state in general terms that he has endeavoured to give a correct account of the growth and mode of development of the colchicum bulbs, pointing out the middle of July as the period at which their medicinal qualities are most conspicuous, and therefore the most appropriate for its pharmaceutical preparation. In his chemical researches he shows that the plant possesses two active principles,—one, *veratria*, as has been stated by Pelletier; the other, a more equivocally crystalline substance, called by Hesse and Geiger *colchicia*. The author has entered minutely into the physiological action of the drug; and attention is specially directed to its effects upon the urinary secretion. The concluding portion of the paper is devoted to the therapeutical actions of the medicine, as a diuretic, a sedative, and a renal alterative in gout and rheumatism. In these latter diseases the author attributes the benefit of the drug to the power it has of increasing the elimination of urea and uric acid from the blood, the reality of which power he demonstrates by several analyses of urine previous and subsequent to its exhibition.

Among other diseases in which colchicum has been used with advantage, are some skin diseases, as urticaria and prurigo; affections of the genito-urinary system; also in tetanus and cholera. A fact of great value, if borne out by experience, is the power of colchicum in restoring the urinary secretion in cases of suppression, and this is the basis of its exhibition in cholera. From its decided action in dropsy following scarlatina the author throws out the suggestion that colchicum might prove serviceable in the treatment of morbus Brightii, more especially in those cases in which coma is threatened from retention of urea in the blood; in such the author expresses his confident conviction that it will prove of eminent service.

We may mention that this elaborate paper is accompanied by a lithograph plate, illustrating the different phases in the growth of the plant.

Lectures on the Diseases of Infancy and Childhood.

By CHARLES WEST, M.D., Fellow of the Royal College of Physicians, Physician to the Hospital for Sick Children, &c. Second Edition, enlarged. London: Longmans and Co.

THE rapid exhaustion of the first edition of Dr. West's valuable lectures affords the strongest proof that, although several excellent monographs on the subject existed, a work was still wanted, which in point of science should place the diseases of infancy on a par with those of adult age. It had long been too much the custom, in this country more particularly, to regard the ailments of young children, either as so simple and manageable as to require no separate study, or, on the other hand, from the difficulties contingent upon the age, so unintelligible as to offer little recompense for that diligent investigation which in other departments of pathology has been followed by such distinguished results. The author of the present treatise has done more than any other to undeceive the profession in both these respects; to show, on the one hand, that the most extended acquaintance with the diseases of adult age will not, in itself, suffice for the successful management of infantile maladies, and, on the other, that by according to these latter the same amount of scientific labour, the practitioner will be rewarded by an equivalent of success which, on a more superficial view, he was not prepared to expect.

We have little doubt that the majority of our readers are well acquainted with Dr. West's admirable lectures, either as they appeared in their original form, or in that of the first edition. As a separate publication, we need, therefore, only remark, that in the present volume the whole work has been carefully revised, and additions, chiefly cases, have been made, to the amount of fifty pages. It is now the most complete treatise on infantile diseases in any language, and we would earnestly advise those who do not possess it, to lose no time in adding it to their library.

Proceedings of Societies.

SOUTH-WALES BRANCH.

At a preliminary meeting of the profession, held at the house of James French, Esq., Neath, on Wednesday, March 10th, 1852, present,—Geo. G. Bird,

M.D., T. A. Essery, Esq., Swansea; T. J. Dyke, Esq., J. Russell, Esq., Merthyr; James Lewis, Esq., Edward Evans, Esq., Cardiff; James Lewis, M.D., Maesteg; H. L. Pritchard, Esq., Tir Caradoc, Taibach; W. Pritchard, Esq., Bridgend; W. G. Jones, Esq., James French, Esq., Neath; J. G. Hall, Esq., W. Rowland, Esq., W. Harris Long, Esq., and W. H. Michael, Esq., Swansea,

It was moved by J. FRENCH, Esq., seconded by H. PRITCHARD, Esq., and resolved,—

“That Dr. Bird take the chair, and preside over the meeting.”

The Chairman having brought before the meeting the correspondence which had taken place on the subject, and made a statement as to the objects and advantages of such an Association;

It was moved by E. EVANS, Esq., seconded by H. PRITCHARD, Esq., and resolved,—

“That it being in the opinion of this meeting desirable to form a MONMOUTHSHIRE and SOUTH WALES BRANCH of the PROVINCIAL MEDICAL and SURGICAL ASSOCIATION, a meeting be held at Swansea, on Wednesday, August the 25th, to take such steps as may be deemed necessary for the attainment of the object. That G. G. Bird, Esq., M.D., be this day elected Provisional President, and that he be desired to preside at such meeting, and also to read an address on the occasion.”

Moved by T. J. DYKE, Esq., seconded by W. JONES, Esq., and resolved,—

“That a General Committee be this day appointed, consisting of the following gentlemen, to carry out the resolutions of this meeting, and that W. H. Michael, Esq., be elected Honorary Secretary, *pro tem*:—

“List of Committee.—W. Rowland, Esq., W. H. Long, Esq., T. A. Essery, Esq., J. G. Hall, Esq., Swansea; J. L. White, Esq., Dowlais; James French, Esq., Wm. Jones, Esq., Neath; Dr. Vachell, E. Evans, Esq., Cardiff; J. Russell, Esq., T. J. Dyke, Esq., Merthyr; J. Brewer, Esq., R. F. Wollett, Esq., Newport; Dr. Morris, Thomas King, Esq., Chepstow; E. Y. Steele, Esq., F. C. Batt, Esq., Abergavenny; Dr. Price, S. Wilson, Esq., Monmouth; Nathaniel Coates, Esq., Tredegar; James Essex, Esq., Pontypool; Dr. H. Lucas, Crickhowell; Dr. Prest. Lucas, Brecon; — Thomas, Esq., Llangattock; Dr. Lawrence, J. Rowland, Esq., Carmarthen; Dr. Frothero, Llandilo; Benjamin Thomas, Llanelly; H. Pritchard, Esq., Aberafon; W. Pritchard, Esq., Bridgend; Dr. Lewis, Maesteg; Dr. Silvester, Cowbridge.

Moved by W. ROWLAND, Esq., seconded by W. PRITCHARD, Esq., and resolved,—

“That the gentlemen now present having enrolled their names this day as Members of the Monmouthshire and South-Wales Branch of the Provincial Medical and Surgical Association, they, together with the Committee, be requested to obtain further signatures.”

Moved by W. H. LONG, Esq., seconded by J. RUSSELL, Esq., and resolved,—

“That the President and Committee be requested to make such arrangements as may be necessary for holding the first meeting of the Association at Swansea.”

Moved by J. LEWIS, Esq., seconded by T. A. ESSERY, Esq., and resolved,—

"That the best thanks of this meeting be given to Sir Charles Hastings, of Worcester, for his kindly-expressed willingness to be present (if in his power) at the first meeting of the Association, and that a cordial invitation be sent him in the names of the President and Committee."

Moved by W. ROWLAND, Esq., seconded by J. FRENCH, Esq., and resolved,—

"That each member of the Branch be entitled to invite (at his own expense) a friend to the dinner of the Association, giving notice thereof to the Committee a fortnight before the day fixed (August 25th); and that the Committee be authorised to invite persons of distinction, both in and out of the profession, at their discretion."

Moved by J. FRENCH, Esq., seconded by J. RUSSELL, Esq., and resolved,—

"That it is highly desirable and important to incorporate a Medico-Ethical Society, in connection with, and as part of this Branch; and that the gentlemen present do form this Committee, with power to add to their number; and that they be requested to bring up a report, together with rules and regulations, for the said Society, for the consideration and approval of the first general meeting of this Branch Association."

(Signed.) GEO. GWYNNE BIRD, M.D.,
Chairman.

Dr. BIRD having left the chair,—

It was moved by J. LEWIS, Esq., seconded by H. PRITCHARD, Esq., and carried by acclamation,—

"That the best thanks of this meeting be given to Dr. BIRD for presiding on this occasion, and for the trouble he has taken in arranging the preliminaries of this meeting."

W. H. MICHAEL,
Honorary Secretary, *pro. tem.*

BIRMINGHAM PATHOLOGICAL SOCIETY.

NOVEMBER 6, 1851.

T. W. WILLIAMS, ESQ., IN THE CHAIR.

Nearly complete destruction, by Necrosis, of one Temporal Bone, with the Nerves connected with it; Sloughing of the Dura Mater; a Sloughing Channel through the side of the Brain into the Lateral Ventricle; destruction of the Septum Lucidum.—By DR. RUSSELL.

Mrs. PEYTON, aged 66, married; a nurse. August 10, 1851. The history she gave me is as follows:—About seven or eight months ago she was first attacked with pain in her right ear, and about the same time the parts in front of the ear swelled considerably. She attributed it to exposure to cold. About a fortnight after the pain attacked her, she struck her ear against a bracket, and in a day or two "the gathering burst," and a good deal of discharge flowed from the ear. Neither the discharge nor the pain has ever ceased

since; the discharge has never intermitted for more than a day or two, and its temporary cessation always greatly aggravated the pain; it was very foetid; sometimes half a table spoonful of pure blood would flow from the ear, or a quantity of blood and water. About a fortnight before I saw her, a piece of bone came away "like the mallet bone." The pain has continued very severe; it commenced over the root of zygoma, in front of the ear, and radiated over the side of the head, as far as the coronal suture, and across the whole occipital region; in the latter part it has always been especially bad; she often sat for hours pressing her head between her hands. On March 30, (Mid-Lent Sunday), whilst on a visit to her daughter, she first noticed some paralysis of the right side of the face, and this paralysis has since increased. She has never had discharge from her ear before; though I learnt that she was for a long time in the habit of picking her ear with a pin, but not from any uneasy sensation there that I could learn. Her family is free from consumption, and there is no sign of syphilis in her history. At my visit I found her a well made woman, one who had been of full habit. The right side of her face was paralyzed; the muscles supplied by the portio dura had nearly lost all power, though she could partially close the right eye, and quite shut it during sleep. The mouth was a little drawn to the left, but when pursed up the left side only moved. The buccinator also was paralyzed, but not perfectly, as food did not collect in the cheek; the cheek, however, hung loosely, and flapped in her talking. Mastication was impaired; she could only eat sopped food; how far this interference was due to loss of muscular power in the pterygoids and other muscles, I could not say, on account of the disease around the maxillary joint. The tongue was protruded in a right line; its right half was quite insensible; the left half quite sensitive. The other parts supplied by the sentient branches of the fifth retained their sensibility unimpaired. The senses were perfect, excepting that hearing was destroyed in the right ear. The pupils were natural. There was no sign of paralysis elsewhere. Speech was a good deal affected by the facial paralysis. There was a soft diffused swelling in front of the right ear, over the root of the zygoma; it was not particularly tender, and did not fluctuate. The tragus and the auditory cartilage were both exceedingly thickened and excoriated, and there was a constant sanious foetid discharge from the ear.

At my two first visits she was in a state of mania, pushing away her friends with violence and uttering loud complaints. She had these fits for three days only. Her hands and arms were tremulous from having worked at gilding years ago. I referred the mania to constant intense pain, which had deprived her of rest entirely. Her pulse was feeble, her surface chilly. R. Morph. Mur., gr. $\frac{1}{2}$ dolor urgent.—R. Mist. Am. Camph c \AA there.

September 2nd.—Mr. Bindley, who kindly gave me much assistance in the case, succeeded to day in passing a probe through the cartilage of the meatus in front; the instrument passed freely under the skin covering

the root of the zygoma in all directions; he accordingly cut down upon the point of the probe, and having then pushed it through the incision, found that it went very deeply down, and that he could detect bare bone. A day or two before a small piece of bone had been passed at the meatus auditorius.

October 6th.—She died this evening. No relief of consequence followed the incision; pus of a sanious character flowed pretty freely through it, and at times she described a very large watery discharge. Her physical powers became impaired by constant suffering, but she had no return of mania, until the last fortnight, when she was delirious at night, and her memory became confused. Her bodily powers, however, remained unaffected; she was sitting up the day before she died. The pain continued with very great severity and unintermitting constancy; it radiated all over her head. She took half a grain of morphine three times in twenty-four hours, but found only temporary relief; much relief, however, was experienced from rubbing over the seat of pain an ointment of extract of belladonna and Ung. Cere Flavræ of each equal parts. The facial paralysis became complete; the buccinator was also quite paralyzed, food collected in the cheek, and saliva often dribbled from the corner of the mouth. The conjunctiva of the right eye became œdematous and congested from constant exposure, but the paralysis never showed any disposition to extend beyond its former limits. She was sensible to within a few hours of death, when she seems to have become heavy and stupid, tending to a state of coma. The treatment was of course only palliative.

Secio-Cadaveris forty hours after death.—Present, Mr. Brindley, Mr. Carter, and myself. Head alone examined. On the right side of the head the integuments and the entire external ear were quite unattached to the bone; the sides of the interspace were foul and sloughy, and emitted a most foetid stench; the sloughy cavity extended to the base of the skull, and as far back as the mastoid process. The entire squamous portion of the temporal bone was destroyed, except a small portion of the upper part, and the destructive process had encroached upon the mastoid process, laying open the mastoid cells. The petrous portion of the bone was also destroyed, only a few fragments of bone, and shell attached to the basilar process of occipital bone, remaining. A wide irregular opening was thus formed into the interior of the skull, and a wide sloughy cavity at the base of the skull, extending inwards to the parts upon the vertebral column. The sides of this cavity were covered with sloughy granulations, and were formed by the remains of the soft parts around. We noticed all that remained of the facial nerve, passing across the upper part of this cavity, exposed but uninjured; it was the portion contained in the aqueduct of Fallopius, exposed by destruction of the bone; it terminated at either extremity in a mass of granulations. The carotid artery was not affected, though its bony sheath was gone; it was enveloped in a covering of very dense granulations. The dura mater adhered to the bone nearly to the edge of the large opening, where,

exposed by destruction of bone, its outer surface was sloughy. It was perforated by an opening the size of a crown piece, the edges of which were in a state of slough, and from them sprung spongy pale granulations. The dura mater seemed to have resisted the extension of the disease. Its tissue was healthy and glistening internally within a short distance of the sloughy opening. The orifice of the internal auditory meatus remained, though unattached to any bone, and without a vestige of the portio mollis. The lateral sinus, where lying on the mastoid portion of the temporal bone, was quite plugged with fibrin of a dirty colour, firmly adherent; it did not contain pus. By this clot the closure of the vessel in the lacerated foramen was complete. The eighth pair entered the lacerated foramen as usual; but on the under surface there were no vestiges either of the jugular vein or of the nerves. The fifth pair was entire within the skull, but enclosed in much thickening of the dura mater, which would, probably, have exerted considerable pressure on the nerves. Beyond this the nerves were not dissected; under the circumstances it was impossible to do so. *Brain*:—From the opening in the dura mater a sloughy, irregular passage led through the substance of the brain into the right lateral ventricle, which was half full of sloughy debris of cerebral tissue, and contained a small quantity of a thin purulent fluid at the lowest point of its posterior corner. The left ventricle was almost as full of debris as the right; apparently a communication between the two cavities had been effected by the breaking down of the septum lucidum. With the exception of the neighbourhood of the sloughy passage in the right hemisphere, where the substance of the brain was softened, and infiltrated with foul pus, and of the septum lucidum, the entire brain was healthy. The surface of the right corpus striatum had become implicated, but the destructive process had not penetrated to any depth. The arachnoid and pia mater were generally healthy. There was about two drachms of thin purulent fluid at the base of the brain.

It is not clear, from the history, whether the disease originated in the ear, or external to it; the evidence, as far as it goes, is strongly in favour of an origin external to the ear. The statement of the patient was distinct, that the pain and the swelling in the front of the ear were nearly contemporaneous, and that she never had suffered from discharge from the ear; at the same time all analogy would lead us to refer the starting point of the mischief to the internal ear. The pain, so much referred to the ramifications of the fifth pair, and to their inosculation with the cervical plexus, might have been occasioned by pressure exerted by the thickened tissue around the gasserian ganglion and neighbouring portion of the nerve, but in this respect our dissection is imperfect. The absence of more general symptoms with so much cerebral disease, must be referred, in part, to the great ganglia of the brain remaining intact, in part to the gradual nature of the change. At our Pathological Society lately we had a case in which, with *red ramollissement* of a smaller

portion of brain than was implicated here, the patient died apoplectic. So much more does the effect of disease of the brain upon the structures of the organ depend upon the nature of the process by which the change is effected, than upon the extent of tissue enveloped.

The absence of all apparent symptoms, with destruction of the pneumogastric nerve, is a good comment on the like results of Dr. Reid's experiments on dogs.

Diseased Tibia; Sequestrum.—By Mr. MOORE.

This specimen was obtained from a leg amputated by Professor Knowles at the Queen's Hospital. There were numerous openings leading to dead bone along the whole anterior part of the leg. The ankle-joint was also implicated, rendering any operation for the removal of the sequestrum alone desirable. The preparation shows the sequestrum contained in a partially bony shell, and apparently consisting of the whole anterior part of the tibia; and its smooth and polished appearance where opposite the cloacæ contrasts strongly with the rough deposits forming its shell. The disease seems to have had its origin in an attack of erysipelas two years back.

Hypertrophy of the Tibia.—By Mr. MOORE.

This patient dated the commencement of his disease to a sprain received eight or nine years back. Since that time he had never been able to use his leg, which had gradually attained the following condition. The tibia was found much thickened and enlarged, while the muscles, probably from disuse, were atrophied. There was very little motion of the ankle. There was no sore on the leg, but the integument was shining, reddened, and appeared stretched. He complained of but little pain. The leg was amputated by Professor Parker, and the tibia after being freed from the muscles, &c., was found to be nearly double the size and weight of the healthy state.

Encysted Tumour.—By Mr. MOORE.

This cyst was removed from rather an unusual place for such growths, viz., about one inch and a half external to the anus on the left side. The tumour has nothing remarkable in itself; the cyst was filled with a glairy fluid which, under the microscope, contained some ill-formed bodies, somewhat resembling pus globules. The size of the tumour was that of a small orange.

Sleatomatous Tumour of the Scalp.—By Mr. MOORE.

This tumour was removed from beneath the scalp; it was attached to the periosteum, but whether it had its origin from that structure may be questioned. It is filled with a cheesy material and was alone in its growth.

Scrofulous Caries of the Os Calcis.—By Mr. MOORE.

This specimen was obtained after death from the body of the patient, who died phthisical. There were several openings leading to carious bone about the posterior and outer surface of the os calcis. The illness,

which proved fatal, seemed to have its origin from cold, congestion of the lungs taking place followed by rapid deposition of tubercular matter, as after death (which happened in about a month,) those organs were found stuffed with such material. There is no implication of the ankle joint, the disease being limited to the bony structure.

Chronic Inflammation of the Substance of the whole of the Lungs, producing General Extreme Condensation; Secondary Disease of the Heart; Dilatation, without Hypertrophy; Death from Cardiac Symptoms.—By Dr. RUSSELL.

Samuel Orbell, aged 36, a carpenter. He came under my care as a patient of the Dispensary some time in last May; I, however, do not remember anything of his case, but find it entered, by myself as one of *chronic bronchitis*. He subsequently grew worse, and I did not see him for some time; he was supposed to be dying, but revived wonderfully, and in consequence, Mr. Welch requested me to visit him. I kept no notes of his case. I found that anasarca had come on in the lower extremities, rather suddenly, about five weeks before my attendance began, and had increased rapidly. I found him in bed, unable to lie down from a tickling cough, with only a *scanty expectoration* of mucus. His lower extremities were extremely anasarcaous, and also the integuments of the abdomen. There was no ascites. I found extended cardiac dullness, with feeble impulse, and a dull systolic bellows-sound at the apex of the heart, but the results of my examination of the lungs I do not remember. His face was rather livid. He was not much emaciated, and his appetite continued good. His urine scanty, not albuminous. He has been a very intemperate man, drinking chiefly of ale. In his business he has been much exposed to cold and wet. He has had chest-symptoms for above two years, chiefly a cough, *without much expectoration*; he does not seem to have suffered much from pain in his chest. He never lay by until his last illness, when he came to me; nor had he had anasarca or cedema before.

In the further progress of his case I tried diuretics; then elaterium, alone, with opium, and with calomel, but it did not suit him, always producing violent vomiting. Pulv. Jalep. Co. was quite ineffectual. The very watery stools, however, which were obtained, reduced the dropsical effusion. His cough continued very troublesome and he could never lie down; the constant blueness of the face, which varied, but never left him, prevented my using opiates. The expectoration increased a little. His appetite kept up surprisingly, until within a week of his death. At times during the last three weeks he was violently maniacal, and tried to destroy himself by jumping out of the window or by hanging.

Section—cadaveris sixty hours after death.—The face exceedingly bloated, livid, and loaded with blood, which oozed from the ears and nose; upper extremities also much loaded; decomposition far advanced, although the weather was cold; subcutaneous cellular tissue very oedematous. *Chest:* Lungs both very adherent, the

left universally so; and partially withdrawn from the heart; the apices of both, of the left in particular, were closely united to the chest, and capped by dense false membrane. Both lungs presented the same condition, their tissue crepitated nowhere, it was everywhere extremely tough and firm, and could scarcely be torn. It was of a dull leaden colour throughout, the interlobular divisions being very distinct, though the connecting division was not thickened at all; the lobules were not in the least contracted; the bronchial tubes not dilated; their sides much hypertrophied; the muscular fibres of the primary and larger bronchi were remarkably developed; I never saw them so distinctly; not a *particle of mucus* was met with in the bronchial tubes of either lung. *Heart* twice its usual size, very flabby; its cavities much dilated, but its walls not proportionally hypertrophied; the lining membrane deeply strained throughout; valves healthy; the large vessels were much loaded with fluid blood; the heart also was very full of fluid blood, but it was emptied before the cavities were opened. Abdominal organs congested, otherwise all healthy. The lungs scarcely floated in water; a slice from one of them sunk.

In the *post-mortem* appearances of this case I attach considerable importance to the cough never having been attended by much expectoration, and to the absence of mucus from the bronchial tubes when laid open, in relation to the state of the lungs revealed by dissection. This symptom indicates that the disease did not reside in the mucous membrane of the bronchial tubes, and the *post-mortem* showed evidence of some consolidating process involving the whole proper tissue of both lungs; whilst the pleuritic adhesions evidenced the pre-existence of inflammation, which the consolidated state of the lung confirms. I suspect the disease to have lain in the pulmonary tissue, and not in the tubes. In this respect it differed from chronic bronchitis; it differs also from cirrhosis of the lungs in not implicating the fibrinous element. I believe the disease to have consisted in a process of low inflammation, perhaps of the character of pneumonia notha. Its affecting the entire of both lungs is remarkable, and independently of the history, proves the process to have been slow, and not to have resulted from any acute attack, unless, originally, from bronchitis. The hypertrophy of the tubes, and the development of their muscular fibres are remarkable.

I have notes of a case in all respects similar to this, in which the moving cause would appear to have been the presence of flour in the air. In this latter case some emphysema was superadded, and probably from that circumstance, the lungs floated fully. The cardiac symptoms were less prominent, obviously because the dilatation was accompanied by hypertrophy; hence the pulmonary symptoms had time to produce their full effect on the system, and death took place precisely as from phthisis. In Orbell's case, on the contrary, the patient died of the secondary cardiac disease. In two other cases the pulmonary tissue was in the same state, but combined with large vomicae and milary tubercles.

Larynx of a Girl who died from Choking.—By Mr. HILL.

A large bolus of masticated food, tightly wedged down, filled the pharynx and the opening of the larynx, being driven down into the latter so as to protrude through the rima, the epiglottis was pressed forward against the base of the tongue, leaving the glottis open.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

On the Physiological Origin of the Blood Globule.

Dr. Bennett sums up a valuable paper on the function of the spleen and lymphatic glands, with the following conclusions respecting the genesis of the blood globule:—

1. The blood globules of the vertebrate animals are originally formed in the lymphatic glandular system, and the majority, on joining the circulation, become coloured in a manner hitherto unexplained. Hence the blood may be considered as a secretion from the lymphatic glands.

2. In mammalia the lymphatic system is composed of the spleen, thymus, thyroid, supra-renal, pituitary, pineal, and lymphatic glands.

3. In fishes, reptiles, and birds, the coloured corpuscles are nucleated cells, originating in these glands, but in mammalia they are free nuclei, sometimes derived as such from the glands, at others developed within colourless cells.

4. In certain hypertrophies of the lymphatic glands these cell elements are multiplied to an unusual extent, and finding their way into the blood, constitute a diseased condition—leucocythemia.

5. The solution of blood-corpuscles, conjoined to effete matter, not converted into albumen, constitutes blood-fibrin.—*Monthly Journal of Medical Science*, March, 1852.

SURGERY.

Excision of the Head of the Femur.—By Mr. STANLEY.

This case occurred in the person of a little girl, ten years old, who had been suffering from hip-disease for several years. When admitted into St. Bartholomew's Hospital she was in a very weak state, and it was found that suppuration had taken place around the joint, several fistulous apertures being visible externally. Mr. Stanley stated, before operating, that he felt himself justified, under the present circumstances, in exploring the affected joint, and removing the carious head, if necessary—viz., if it were found in a state of caries or necrosis. If no such interference were found advisable, it would still be a great benefit to the patient that the matter should be given free exit; this, in fact, might save the child's life. Mr. Stanley further added, that he intended to secure the limb with splints while the patient was under the influence of chloroform, as thus a great amount of pain might be spared.

A circular incision was then made over the left hip-joint, the concavity looking inwards; the flap was

raised, and after some careful dissection the neck of the bone was exposed. It was now discovered that one of the abscesses extended far back under the glutæus maximus, and that the purulent accumulation had taken its origin close to the neck of the femur. A portion of the head was now brought into view by rotating the limb inwards, and after a close examination of this process, Mr. Stanley, supported by his colleagues present, determined to remove it. Strong bone-forceps were applied to the neck, the division of which proved very easy, as it was in a very soft state. The head was easily enucleated, and was found, on a section being made, to be utterly disorganized by caries. The cotyloid cavity did not seem free from disease.

Mr. Stanley observed, that this state of parts did not admit of reparation; the head of the femur might be looked upon as dead, for suppuration had broken down the cancelli of the bone. No vessels required tying. The limb was carefully secured, and afterwards wrapped in cotton.

The child has progressed very favourably since. The appetite returned a few days after the operation. The wound assumed a healthy aspect, and the countenance improved. On the tenth day after the excision of the head of the femur, the patient was made to assume the prone position, and a weight hanging from the extremity of the bed was fixed to the foot, so as to counteract contraction of the limb.—*Lancet*, February 14, 1852.

On Injuries to the Spine in relation to the Urinary Organs.—By Mr. BULLOCK.

This was the subject of a paper recently read before the Medical Society of London. Referring to the important changes which are observed in the urinary secretion after injuries to the spine, Mr. Bullock observed that there were two opinions as to the state of the urine,—one, that it was secreted alkaline by the kidneys; the other, that it acquired its alkalinity in the bladder. In support of the latter view, he said, that owing to the nerves supplying the bladder being paralyzed, the urine was retained, and, although it might be drawn off frequently by catheter, yet a little would always be left, which would irritate the bladder, and cause it to throw out more mucus than natural, which setting up a catalytic action, induced the decomposition of urea and the formation of carbonate of ammonia, which, by neutralizing the solvent acid, threw down the phosphates. He had washed out the bladder when the urine was alkaline, and then allowed it to accumulate, when it was drawn off again as long as seven hours afterwards, and was found to be acid. At *post-mortem* examinations the urine had been squeezed out of the tubules of the kidneys, and found to be acid. He did not think, with Mr. Stanley, that the spinal marrow, through its connexion with the sympathetic, had that influence over nutrition, secretion, and excretion, which would be implied if alkalinity of the urine was dependent upon the effect produced on the kidney by the cutting off the supply of spinal nerves, but rather that there were, in the sympathetic system of nerves, organic or gelatinous fibres, which regulate the molecular changes which take place in the various processes of nutrition, secretion, &c. In other cases, where there was no

injury to the spine, but where the urine was retained in the bladder a length of time, there was alkaline urine—in cases of stricture, for instance. It was important, he observed, that the bladder should be frequently washed out, and all sources of irritation to it avoided; for cases of injured spine sometimes proved fatal, not from the injury to the spinal marrow, but from disease of the bladder, which might even extend up to the kidneys. He considered that the cause of the retention of urine was the existence of elastic tissue at the neck of the bladder, without admitting which, it would be difficult, if not impossible, to explain why there should be retention of urine and incontinence of feces, the muscular fibre of the bladder and of the sphincter ani being both supplied by spinal nerves. The torpid state of the bowels would tend to show that the movements of the intestines were dependent in some degree on the spinal system, probably through the connexion of the sympathetic with the roots of the spinal nerves, but yet that they were not entirely regulated by spinal filaments; and also what were under the control of the spinal system were dependent on those filaments which terminate in the spinal cord, that they were not voluntary but reflex actions. Another point was, that the formation of bed-sores was not in a great degree dependent on the cutting off the supply of spinal nerves, but more the result of the uninterrupted pressure consequent on the loss of the power of changing the position in the slightest degree, for that uninterrupted pressure very quickly produced sloughing in a perfectly healthy subject, thus assisting to show that the spinal marrow had very little to do with the function of nutrition.—*Ibid*.

MIDWIFERY.

On the Uterine Sound or Bougie.—By Dr. HIGGINS.

The intention of this paper is to vindicate this instrument and its talented inventor, Dr. Simpson, from the extraordinary, and we believe, unmerited accusations brought against it in the anti-speculum agitation now going on in the Medical Society of London. In fulfilling his object the author proposes three subjects of inquiry:—1. What is the uterine sound or bougie? 2. In what class of cases is it used? 3. Is its use justifiable.

In reply to the first question, he shows that it is an instrument made of German silver and therefore does not come under the denomination of an "iron prong," as it has been called.

To the second question he replies that there are some cases in which diagnosis is imperfect without its use. One of them is amenorrhœa dependent on imperfect uterine development. Here he observes that the use of the instrument, by which the existence of a short and undeveloped uterus would be ascertained, is most valuable; and would spare the patient the useless and disappointing persistence in "forcing" medicines. It will also demonstrate the existence of occlusion of the cervix, as well as the displacements known as retroversion and retroflexion. It likewise forms an important element in distinguishing between uterine polypi and inversion of the womb. Again, in the early stage of ovarian disease, much assistance is to be derived from its employment.

The last point to which the author refers is the use of the instrument in furthering the ends of justice. This he illustrates by the case of a woman who was charged with infanticide. The accusation could not, however, be brought home to her, from the absence of all proofs of recent delivery. By means of the sound an unusually enlarged uterine cavity was discovered, and this fact eventually led to investigations which clearly established the woman's guilt.

As to the justifiability of the use of the instrument, the author points out that this is demonstrated by his foregoing observations; he moreover considers that there is no more *primâ facie* evidence of the danger of introducing an instrument into the womb than into the bladder; on the contrary, that the bladder is the more sensitive viscus of the two, and therefore more likely to be injured. Speaking of his own experience, Dr. Higgins states, that he has used it and seen it used for years, and has never met with an instance of mischief arising from it.—*Medical Times and Gazette*, Feb 21.

Prolonged Secretion of Milk.—By Dr. KNEELAND.

Dr. Kneeland reported the following case to the Boston Society for Medical Improvement:—A lady, aged 35, had her first and only child five years since. Her husband died when this child was three weeks old, and she has not been again married. She nursed her child for two years, during which period the flow of milk was so profuse that if she were absent two or three hours from the child, her dress would be completely wet; to use her own expression, "the milk would run down into her shoes." Her child died at the age of two years, of chronic hydrocephalus; since then, up to the present time, a period of three years, there has been a constant secretion of milk in her breasts, and so free as often to wet her dress quite through. During the last week she was able to express, by gentle pressure, a perfect stream of milk. She has been, and still is, regular in her menstrual periods, and also enjoys perfect health.

Dr. Channing alluded to two cases, in one of which milk continued to be secreted for eight years, in the second four years. He did not seem conversant with the nervous symptoms induced by prolonged lactation, which are so familiar to practitioners in this country.—*American Journal of Medical Sciences*, January, 1852.

TOXICOLOGY.

Poisoning with Oil of Tansy; Death in Three Hours and a Half.—By JOHN DALTON, M.D., Boston, U.S.

The subject was a girl, aged 21. One morning on entering her room a strong odour of tansy was perceived, which led to the suspicion that she was pregnant. Next day she dined heartily at five P.M., and went up stairs soon after nine. The girl's manner was natural and cheerful. At eleven a loud scream was heard, and on entering the patient's room she was found insensible, and strongly convulsed. She was seen immediately by the narrator of the case. The girl was then lying on her back by the side of the bed, and presented the following appearances:—Total unconsciousness; cheeks flushed, of a bright red colour; eyes open, and very brilliant; pupils of equal size, widely dilated, and

immovable; sclerotics injected; skin warm, not remarkable as to moisture; respiration hurried, laboured, stertorous, and obstructed by an abundance of frothy mucus, which filled the air-passages, and was blown from between the lips in expiration; the breath had a strong odour of tansy, as had been already observed by Dr. Morrill; pulse quite full, forcible, 128; at intervals of five to ten minutes the body was convulsed by strong spasms, in which the head was thrown back, the respiration suspended, the arms raised and kept rigidly extended, and the fingers contracted. After this state of rigidity had continued for about half a minute, it was usually succeeded by a tremulous motion, often sufficient to shake the room, together with very faint and imperfect attempts at inspiration. The whole interval, from the commencement of the convulsion to the first full inspiration, varied from a minute to a minute and a half. Occasionally the tongue was wounded by the teeth, and the saliva slightly tinged with blood. Immediately after a convulsion the countenance was very pallid and livid, from the suspension of respiration, and the pulse exceedingly reduced in strength and frequency. The pulse and colour then gradually returned until the occurrence of the next spasm. It was very common, a few seconds after the termination of a convulsion, for the head to be drawn slowly backward, and the eyelids, at the same time, stretched wide open. In the intervals of the convulsions the limbs were mostly relaxed, but the jaws remained clenched. She was bled, and had an emetic, without relief, and died at a quarter-past two A.M.

The autopsy showed nothing abnormal in the brain, nor in the chest; the latter cavity exhaled a strong odour of tansy. The stomach contained twelve ounces of semifluid, yellowish substance, consisting of half-digested food, mixed with quantities of oil globules, smelling strongly of tansy. There was no great vascularity, or other morbid appearance. The uterus contained a fetus of four months.

It was subsequently ascertained that the girl had taken an ounce and two drachms of the oil, which she had obtained under a false pretence. Dr. Dalton considers that the poison was taken immediately before the scream was heard, which would give three hours and a half till the time of death.—*American Journal of Medical Sciences*, January, 1852.

[It does not appear that oil of tansy is much known as a poison, since Mr. Taylor makes no mention of it in his compendious work on "Poisons." In America it would seem to be occasionally used, as in the present case, to produce abortion.]

Poisoning with Corrosive Sublimate.—By Dr. THOMPSON, Perth.

Dr. Thompson relates the case of a man, aged 50, of intemperate habits, who was admitted into the Perth Infirmary at nine A.M. of July 9th, complaining of severe epigastric pain, increased by pressure; intense thirst, and difficult deglutition. He appeared to be suffering from intense salivation. The interior of the mouth was sloughy, and the tongue was much swelled. He stated that he had taken arsenic, but it was subsequently discovered that he had swallowed two drachms of corrosive sublimate the previous day. The poison was taken in substance. He stated that the first symp-

toms were pain in the mouth and throat, with swelling of the fauces; constant burning sensation in the stomach; vomiting, and bloody diarrhoea. The treatment was, the administration of white of eggs in milk, and leeches to the epigastrium. His death was sudden.

Sectio-cadaveris.—Mouth, fauces, and pharynx inflamed, with grey sloughy patches; mucous membrane of the mouth and fauces vascular; stomach bright red, chiefly at the cardiac extremity, as were also the duodenum and ilium, and more particularly the sigmoid flexure of the colon; lungs congested, and filled with frothy mucus. Other organs healthy.

Dr. Thompson observes, that we have here a good example of the effects of corrosive sublimate in large doses, and that the unfortunate result was only to be expected where a great delay had arisen in the application of the proper treatment.—*Edinburgh Monthly Journal*, December 1st.

Correspondence.

TREATMENT OF THE INSANE.

To the Editor of the *Provincial Medical and Surgical Journal*.

"Mens sana in corpore sano."

SIR,—Dr. Burgess, in some clever observations "On the Policy and Physiology of Insanity," communicated to the *Lancet*, begins his letter in the Saturday number for February 21st with these words:—"Mental physiology is a new science." To this I must demur: it is a science which has much occupied the attention of old writers. Nor do I discover much light thrown upon it by the reflections of the moderns; indeed their volumes, like the Arabians, seem to be but copies of foregone opinions. It is true anatomy has made great progress, and physiology has kept closer company with her than formerly. Functions appear to have been certainly traced to particular nervous centres, but this, as yet, imparts no knowledge of insanity. No one in dissecting a brain can diagnosticate that the subject was mad, and therefore we are yet left to the conclusions that our own experience in the different forms of this disease has taught us. Then, what opposite modes of medical treatment have been proposed?—what different plans of moral management have been developed?—and yet the success upon the average has been the same. Few chronic cases, compared with recent ones, recover, showing that when taken in time there is a tendency to recovery. Wherever there has been delay, so as to establish lesion of function—whatever organ or part of the brain may have been affected—wherever may be the seat of mind, the morbid impressions of ideas and actions remain unbroken. Many organic diseases bear the same character. My business is, however, more with the management of the insane.

Much has been written upon the subject of restraint, and contrary opinions have been offered. I have no doubt the less you can require it the better, but sound practice is not to be seduced by a mawkish philanthropy. Whatever may be the merit of a more modern claim, the adoption of milder measures, and of less restraint,

was instituted at the Friend's Retreat, near York, and probably has led to the endeavour of a greater extension of such a mode of treatment. I have elsewhere expressed an opinion, that in chronic cases less restraint may be required, the duration of the paroxysm becomes known, and the amount of injury likely to be inflicted more subject to calculation, but in both chronic and recent cases I am certain it is a mode of treatment highly necessary, highly important, and that a most valuable auxiliary, both to the safety and comfort of the patient, is lost by its neglect. I have now two patients who request at times the investiture of the restraint dress; it has often proved a moral remedy. There are many patients who will behave extremely ill for the purpose of creating annoyance and vexation, who know perfectly well what they are about, yet tear their clothes, break windows, and commit dirty actions, secure in their condition as lunatics. The restraint imposed awakens a sense of shame; without any confession of fault, they frequently become more orderly, and more submissive to proper control. In cases where safety is involved, it becomes a solace both to the mind of the patient and of the attendant.

Books, music, and exercise, are recreations that should always form part of the management of the class of private patients I allude to. Good food and good manners are important adjuncts. Conversation with one another is a difficult point in a small asylum, more so than in a large one; the observations of one may poison the minds of many, but with an intelligent attendant sitting in the room, (and I speak more particularly of a female community,) such permission may be serviceable. I cannot think the dancing exercises, lately introduced, will contribute much to the cure. I should imagine the ball would lead to too much excitement, and promote extravagance of many feelings; I have not, however, had much experience in the matter, and in a small asylum it can hardly be effected. I confess I am in the habit of allowing visits to horticultural fêtes, to morning concerts, and occasionally to some sight-seeing at a distance, I may, therefore, be presumed not to be any enemy to amusements properly conducted. On the whole I prefer tranquillity, and the comforts and employments of home, for those who are slight under my care. My maxims have ever been to produce a cure where I possibly can, and as soon as I can; where I cannot, to sooth, to tranquillize, and to make the subject feel as happy as the nature of the malady will permit.

Medicine I believe to have very little effect upon unsoundness of mind, as such. In some of the acute forms of mania antiphlogistic remedies may be required; but it appears now to be generally admitted that depletory measures should be cautiously used. If other diseases affect a lunatic, such diseases must be subjected to the proper laws of treatment; but I know of no physis to minister solely to a mind diseased.

There are many practitioners who consider themselves equal to the treatment of insanity, especially in its violent form; but I can assure those unaccustomed to this department of practice that they will be often mistaken, and will produce much harm where they intended to effect great good.

I have run through the circle of management, not

supposing I had anything new to communicate; on the contrary, I believe every well regulated asylum has its plan based upon the same foundation. My reasons for so doing were to afford some argument that the inquisitorial supervision now established by law was not wanted. I will say nothing of the power it creates; but it is opposed to medical experience, and imposes the supposition of trust-unworthiness. As to medical experience, it is distinctly true that lunatic patients ought not to be subject to frequent interviews; and, again, am I to lay my knowledge at the feet of extra-investigators, and to crave information where I cannot want it. If so, why not extend it to every department of the profession, and let no case be conducted without an overseer?

In regard to the suspicion, I must share in common the feelings of my associates in the practice of this branch of disease that affects humanity; but I repel with indignation the reasons that have been stated for the establishment of this system. Something may go wrong somewhere, and no commission has ever yet put everything to rights; but it is hard that well-regulated houses should be included in the same category. I know that in many instances the relatives and friends of patients feel this. They do not admire the frequent exposure. We all know with what jealousy insanity is considered; and though we are only beginning to open our eyes to the fact, that though insanity, like many diseases, is hereditary, yet, like other diseases, it frequently arises from accidental causes; is cured, and never returns. The care of lunatics, especially of a private class, is of a sacred trust, and should be kept so.

The regulations of the Commission impose a great deal of unnecessary trouble, especially the rules for the management of the case-book, which would seem to be best fitted for the recruiting office. I will be bound to say its statistics for the next ten years will not furnish facts from which any principle of sound knowledge or of better treatment will be deduced. If we are to be governed by the novelties of the day,—if the dicta of Commissioners are to be our polar guide, may we not have homœopathy and mesmerism to direct our steps?

The more I reflect upon the wonderful combination of mind and matter,—the more I reflect upon their mutual action, the more I am astonished at the effects of this mysterious disease; also the more certain I am the greater the quietude and the less of interference are the more rational modes of treating it. Let property be well considered—let all arrangements respecting the domicile, the comforts and the proper care of the lunatic, be closely investigated; but do not let the patients be subjected to multiplied interrogations, nor the managers of their condition—anxious to perform their very responsible duties—suspected of other motives, and placed in a certainly somewhat degraded condition, (for the approval or disapproval of inspectors into your own modes of medical treatment is assuredly somewhat degrading) be allowed, nor overlooked by searching eyes, whose salary must depend upon their power of fault finding.

I read these remarks to an intimate friend, who approved them. As I was on the point of folding up my paper, he said,—“Yet, nevertheless, I should like to be a Commissioner.”

“Thou power supreme, whose mighty scheme,
E'en human woes fulfil,
Here firm I rest, they must be best,
Because they are Thy will.”

The Almighty power that has allowed ills and diseases to appear among mankind has also permitted human means of alleviation. But the best gifts of Providence are often spoiled by our want of common sense in using them.

Yours obediently,
E. B.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I hope you will permit this very short letter to appear in your next number.

I have just finished reading Mr. Perceval's letter to you, and I again aver that his name was never mentioned by me, nor intended to be so, until he forced himself upon my notice. Mr. Perceval's knowledge of insanity appears to be very slight, and his acquaintance only with cases of the most melancholy description. May I advise him to enlarge his map and to extend his survey before he attempts establishing new institutions and generalizations from a few instances. “There is a zeal beyond knowledge.” The late Mr. Sidney Smith advised that gentlemen taking up what they did not understand, should be treated as you would treat a child, whom you found playing with a valuable china bowl!!

Yours obediently,
E. B.

THE ROYAL COLLEGE OF SURGEONS AND HOMŒOPATHY.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—The Council of the College of Surgeons have sent the following reply to the memorial of the medical men of this town and neighbourhood, praying them to express some opinion on the doctrine and practice of homœopathy:—

“College of Surgeons,
“9th March, 1852.

“SIR,—I am desired to acquaint you that your communication, enclosing copies of resolutions of a meeting of the medical profession of Hull and its neighbourhood, held in the Hull General Infirmary, on the 6th of January last, on the subject of homœopathy, has been laid before the Council of this College, and that the Council, after mature deliberation, consider it inexpedient to interfere in the matter.

“I have the honour to be, Sir,

“Your obedient Servant.

“EDMUND BALFOUR, Sec.”

The Members of the College will hence perceive that they must not look to their nominal head for sympathy or assistance in the humiliating contest which they are compelled to maintain with this impudent but successful imposture.

I remain, Sir, your obedient Servant,

HENRY COOPER, M.D.

Hull, March 16, 1852.

THE NEW MEDICAL BILL.

To the Editors of the Provincial Medical and Surgical Journal.

GENTLEMEN,—I stated to the Council of the Bath and Bristol Branch of the Association, that I considered the Medical Reform Bill, as first brought out by the Association and published in the *Journal*, was the nearest perfection of any that had been brought before the public and the profession; and with this I should have been content, had I not seen your remarks on the subject in the last *Journal*. I cannot agree with you that because Sir George Grey has left the Home Office, that “we have no hope of proceeding with the measure during the present Parliament.” If we can frame a bill to the satisfaction of *ourselves*, I do not think we have to fear the opposition in either House of Parliament. Our opponents are the interested in our own body; and if the corporate bodies and colleges are satisfied, the bill ought to be *immediately* brought before the House of Commons, and should they sit long enough, we may have a fair chance of success. There are not two men in the House of Commons or the country, who know the wants of the profession, and understand the subject of Medical Reform better than two Secretaries of State for the Home Department, Sir James Graham and Sir George Grey, who are both in the House of Commons. Let a communication be opened with them at once, and urge one of them to take charge of the bill; they will not require much prompting. Mr. Bell seems to be going on with his Pharmacy Bill. This should stir us up to be looking to ourselves and our own interest.

I am, Gentlemen, yours, &c.,

GEORGE KING,

Bath, March 22, 1852.

Medical Intelligence.

LEICESTER MEDICAL BOOK SOCIETY.

The President of the Leicester Medical Book Society has forwarded to us the following resolution, which was unanimously adopted at a large meeting of the Society, on the 1st of March instant.

Resolved unanimously,

“That the Society views with satisfaction the declarations of several professional bodies against homeopathy, and pledges its members alike to repudiate the nonsensical doctrines of Hahnemann and of Priesznitz; and to decline consulation with those who profess such deceptive absurdities.”

MEDICAL BENEVOLENT FUND.

The dinner in behalf of this Fund is announced to take place at the London Tavern on Thursday, May 20th; and from the first list of stewards already published, we feel confident that it will receive the support of the entire profession.

MEDICAL CANDIDATE FOR PARLIAMENT.

Mr. Hartley Kennedy, the author of the well-known work on Cholera, and lately holding a high position in the medical service of India, is a candidate for the Inverness Burghs. The medical gentlemen of the district, it is to be hoped, will cordially support him.

PRINCELY MUNIFICENCE.

Edward Lonlie, Esq., of Milton Hall, Norfolk, who lately died, has bequeathed to University College Hospital, upon the demise of his wife, the whole of his property, which is sworn to be worth £25,000.

BLOOD STAINS.

In concluding the evidence given a short time since at the Marylebone police-court, before Mr. Broughton, in the case of William Styles, Dr. Hassall made the following observations, important in a medico-legal point of view, in reference to blood stains:—“That, while the determination, by means of the microscope, of the nature of blood-stains, even when very recent, formed on cloth, linen, and other soft and porous textures, is usually a matter of considerable difficulty, and is often impossible, the determination of such stains, however old, as are placed on glass, porcelain, wood, and other hard and smooth surfaces, is in general unattended with difficulty, and extremely satisfactory. This difference is to be explained thus: in the one case the fibrin, albumen, and serum of the blood are in part absorbed, and pass into the cavities of the hairs or fibres of the wool or linen; the blood corpuscles are thus deprived of their preservative fluids, and shrink up—become misshapen or disintegrated; while, in the other case, the fibrin and albumen harden around the blood-discs in drying, and thus preserve them slightly altered in form only.” Dr. Hassall stated that he had frequently succeeded in identifying the blood of different animals, preserved on slips of glass, after the lapse of six years. The stains should be examined in white of egg, and not in water.

FRAUDS COMMITTED BY CHEMICAL PROCESSES.

Extensive frauds have lately been committed in France by washing out, by chemical means, the sums inscribed in checks and bills of exchange, and filling up the blanks with larger amounts. No remedy has yet been discovered; several, however, are talked of, amongst them is one by which commercial paper is covered with a multitude of microscopic spots or stars, which cannot be removed without changing the colour of the paper; another is, to put some coloured matter in the body of the paper, of such a kind as to disappear when washed.—*Literary Gazette*.

APPOINTMENTS.

MILITARY.—2nd West India Regiment; Acting Assistant Surgeon T. Llewellyn Nash, M.D., to be

Assistant-Surgeon, vice Clarke, appointed to the staff. Hospital Staff: Assistant-Surgeon Patrick Joseph Clarke, from the 2nd West India Regiment, to be Assistant Surgeon to the Forces, vice Moore, appointed to the 6th Dragoon Guards.

NAVAL.—Assistant-Surgeon John Bernard Richards (1847), at present serving in the Rodney, 90, to be Assistant-Surgeon of the Pioneer, screw-steamer, in the Arctic Expedition. Surgeon James John Louis Donnet (1845) to be Surgeon-Superintendent of the William Jardine convict-ship. Assistant-Surgeon Hart Gunlet, M.D. (1846), recently serving in the Southampton, 50, on the south-east coast of America station, to the St. George, 120, guard-ship of ordinary at Devonport. Assistant-Surgeon Stephen Bowden (1845) from the Britannia, 120, flag-ship on the Mediterranean station, to the Impregnable, flag-ship at Devonport. Acting Assistant-Surgeon David Wilson to the Polyphemus steam-sloop, for service on the coast of Africa.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on Friday, the 12th instant:—Charles Blatherwick, Titchfield, Hants; Charles Dixon, Australia; Wm. Edney, London; Richard Griffin, Buenos Ayres; Edward Vavasour Hemingway, Leeds; Henry Lane, Wedgnoek Park, Warwick; Benjamin Richardson Lawrence, Cheddar, Somerset; Josiah Ramskill, Leeds; John Reynolds Salter, Exeter.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, March 11th:—Edward Parry Beverley, Margate; David Daniel Davies, Carmarthen; George Hymeneus Lovegrove, Gloucester; Arthur Stretton.

Gentlemen admitted members on Thursday, March 18th:—Arthur Newstead Holmes, Pocklington, York; Southmead Lauworthy, Modbury, Devon; Francis Robinson, Ware, Herts.

OBITUARY.

January 11th, at Calcutta, Surgeon Thomas Murray, of the Bengal Medical Service, aged 35.

March 3rd, in Dale Street, Manchester, James Rhodes, Esq., aged 29, one of the surgeons to the Manchester and Salford Lying-in Hospital.

March 11th, at his residence, Henry Street, Tipperary, suddenly, aged 47, William Reardon, M.B., Trinity College, Dublin, M.R.C.S., Eng.

March 16th, at Woolwich, Mr. Edmond Waters, surgeon, aged 76.

March 18th, at Dalston, in the 68th year of his age, Edward Seaton, Esq., Surgeon, R.N., formerly of Rochester.

March 19th, Thomas Gaskell, Esq., M.R.C.S., of Markham Square, Chelsea, aged 61.

March 22nd, at his residence, Argyll Street, Sir Charles Fergusson Forbes, M.D., K.C.H., and Deputy Inspector-General of Army Hospitals, aged 73.

BOOKS RECEIVED FOR REVIEW.

Lectures on the Diseases of Infancy and Childhood. By Charles West, M.D., &c. Second Edition. London: Longmans and Co., 1852.

On the Diseases of the Bladder and Prostate Gland. By William Coulson, Surgeon to St. Mary's Hospital. Fourth Edition. London: Churchill, 1852.

Lectures on Clinical Medicine. By John Hughes Bennett, M.D., F.R.C.S.E. No. 6.

On Syphilis, Constitutional and Hereditary, and on Syphilitic Eruptions. By Erasmus Wilson. London: Churchill, 1852.

Sketches of Brazil, including New Views of Tropical and European Fever, &c. By Robert Dundas, M.D., &c. London: Churchill, 1852.

On True and False Spermatorrhœa. By Dr. Pickford, of the University of Heidelberg. Edited by Chirurgus. London: E. Churton, 1852. Pamphlet.

London University Calendar, 1852.

Varicose Veins and Varicose Ulcers. By T. W. Nunn, Surgeon to the Western Dispensary. London: Renshaw, 1852.

The Principles and Practice of Surgery. By W. Pirrie, F.R.S.E., Regius Professor of Surgery in the Mareschal College of Aberdeen. London: J. Churchill 8vo, pp. 952.

Remarks on the Pathology and Treatment of the Deformities of the Human Body. By John Bishop, F.R.S. London: Highley and Son, 1852.

Lateral Curvature of the Spine; its Causes, Nature, and Treatment. By R. W. Tamplin, F.R.C.S.E. London: J. Churchill, 1852.

The Stomach and its Difficulties. By Sir James Eyre, M.D. London: J. Churchill, 1852.

Observations upon the importance of Establishing Public Hospitals for the Insane of the Middle and Higher Classes; with a Brief Exposition of the Nature of Insanity, and the present Provision for the Treatment of the Insane. By Thomas Dickson, L.R.C.S.E., London: Churchill, 1852. Pamphlet.

A Letter to the Right Hon. Sir George Grey, Bart., M.P., Her Majesty's Principal Secretary of State for the Home Department, &c., on Medical Registration, and the Present Condition of the Medical Corporations. Second Edition. London: Jackson, 32, King Street. Pamphlet.

On the Fallacies of Homœopathy, and the Imperfect Statistical Inquiries on which the Results of that Practice are Estimated. By C. H. F. Routh, M.D., M.R.C.S. Pamphlet. London: H. K. Lewis, 15, Gower Street, North.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

The Twentieth Anniversary Meeting of the Association will take place this year at Oxford, on the 21st and 22nd of July. The appointment is made rather earlier than usual, in consequence of an intimation from the authorities to the effect that it would be more convenient to the University to have the meeting held before the end of that month.

JAMES P. SHEPPARD, Secretary.

Worcester, January, 1852.

ERRATA.—In Mr. Solomon's last lecture, page 85, col. 1, ten lines from the bottom, for "bodily diseases," read "*diseases of the body*."—Page 86, col. 2, fourteen lines from the bottom, for "*steruntories*," read "*sternutories*."

In Dr. Merei's last lecture, in directing the preparation of the senna-tea, it is stated that the leaves are to be acted upon by "proof spirit." It should have been "*alcohol or rectified spirit*."

TO CORRESPONDENTS.

Communications have been received from Scrutator, Dr. Reid, Dr. Merei, An Admirer of Truth, and Mr. Bryan.

THE NEW EQUITABLE

LIFE-ASSURANCE COMPANY.

INCORPORATED BY ACT OF PARLIAMENT, 7 AND 8 VIC., CAP. 110.

TRUSTEES.

SIR JAMES DUKE, Bart., Alderman, M.P. for the City of London.
JAMES WYLD, Esq., M.P. for Bodmin.
WILLIAM FERGUSSON, Esq., F.R.S., Surgeon in Ordinary to H.R.H. Prince Albert; Professor of Surgery to King's College, London.

GEORGE JAMES GUTHRIE, Esq., F.R.S., late President of the Royal College of Surgeons; Consulting-Surgeon to the Westminster Hospital.
SIR CHARLES HASTINGS, M.D., Founder of the Provincial Medical and Surgical Association of England, and President of the Council.

DIRECTORS.

CHAIRMAN OF THE BOARD.

ROBERT LEE, M.D., F.R.S., Savile Row, Burlington Gardens.

DEPUTY CHAIRMAN.

GEORGE BEAMAN, Esq., M.R.C.S., King Street, Covent Garden, and Hampton Wick.

CONSULTING PHYSICIANS.

MARSHALL HALL, M.D., F.R.S., Grosvenor Street, Grosvenor Square.

CHARLES J. B. WILLIAMS, M.D., F.R.S., Holles Street, Cavendish Square.

JAS. ARTHUR WILSON, M.D., Dover Street, Piccadilly.

CONSULTING SURGEONS.

WILLIAM FERGUSSON, Esq., F.R.S., George Street, Hanover Square.

J. RANALD MARTIN, Esq., F.R.S., Grosvenor Street, Grosvenor Square.

SAMUEL SOLLY, Esq., F.R.S., St. Helen's Place, City.

SURGEON AND MEDICAL EXAMINER.

THOMAS WAKLEY, Esq., F.R.C.S., Guildford Street, Russell Square.

STANDING COUNSEL.

SIR ALEXANDER COCKBURN, Her Majesty's Attorney-General.

GEORGE WOODYATT HASTINGS, Esq., Paper Buildings, Temple.

SOLICITORS.

Messrs. BELL, STEWARD, and LLOYD, 59, Lincoln's-inn-fields.

BANKERS.

THE COMMERCIAL BANK OF LONDON.

SECRETARY.

H. BARBER BEAUMONT, Esq.

CONSTITUTION AND REGULATIONS OF THE COMPANY.

CAPITAL.—MUTUAL ASSURANCE.

The "NEW EQUITABLE" embraces all the advantages of a strictly Mutual Office, with the addition of an ample subscribed paid-up capital, forming a *bond fide* security for its policy-holders.

POLICIES INDISPUTABLE.

The Policies of this Company being Indisputable, they become as readily negociable, in monetary transactions, as any other description of personal property.

SPECIAL ASSURANCES.

All the different varieties of Life Contingencies may be provided against by Assurances in the New Equitable; and every accommodation is granted to the Assured for payment of premium.

INVALID LIVES

Are assured at rates adapted to the circumstances of each case. Every circumstance affecting the health impartially considered.

DIVISION AND APPROPRIATION OF PROFITS.

The whole of the Profits will be Equitably Divided amongst the holders of Policies issued on the participating scale.

MEDICAL PRACTITIONERS.

The Directors feel strongly that Medical Practitioners have not hitherto received that recognition, by Assurance Companies, which their professional knowledge, position, and valuable services entitled them to expect. They have determined, therefore, to frankly acknowledge and consult all duly qualified Medical Referees as the Medical Advisers of the Company, and uniformly transmit, with the Questions intended to be made the basis of every Official Medical Report, A CONSULTATION FEE OF TWO GUINEAS.

ANNUITIES AND ENDOWMENTS GRANTED.

Any further information may be had on applying personally, or by letter, to the Resident Director or Secretary.

CHIEF OFFICES—WEST STRAND, CHARING CROSS, LONDON.

TO PROVINCIAL MEDICAL AND SURGICAL PRACTITIONERS.

THE FOLLOWING ARE

THE PRINCIPAL OBJECTS

TO WHICH THE ATTENTION OF THE

PROVINCIAL

MEDICAL AND SURGICAL ASSOCIATION

IS DIRECTED.

1st.—Collection of useful information, whether speculative or practical, through Original Essays, or Reports of Provincial Hospitals, Infirmaries, or Dispensaries, or of private practice.

2nd.—Increase of knowledge of the Medical Topography of England, through statistical, meteorological, geological, and botanical inquiries.

3rd.—Investigations of the modifications of Endemic and Epidemic Diseases, in different situations, and at various periods, so as to trace, so far as the present imperfect state of the art will permit, their connections with peculiarities of soil or climate, or with the localities, habits, and occupations of the people.

4th.—Advancement of Medico-Legal Science, through succinct reports of whatever cases may occur in Provincial Courts of Judicature.

5th.—Maintenance of the honour and respectability of the Profession, generally, in the Provinces by promoting friendly intercourse and free communication of its Members, and by establishing among them the harmony and good feeling which ought ever to characterise a liberal profession.

THE FOLLOWING ARE THE LAWS, AMONGST OTHERS, OF THE ASSOCIATION:—

PAYMENT OF SUBSCRIPTIONS, &c.

23rd.—Each Member of the Association to pay one guinea admission, and the same amount annually afterwards; the subscription to commence from the first of January each year, and to be considered as due, unless notice of its being withdrawn be given to the Secretary or Secretaries antecedently to the year for which it would be payable; for such subscription each member shall receive a copy of each publication* of the Association issued for the general use of the Members.

24th.—That those Members who have not an opportunity of paying their subscriptions to a Member of the Council resident in their district, are requested to pay it through the medium of their own bankers, to Messrs. Roberts and Co., London, for Messrs. Berwick and Co., Worcester, to the credit of the Association, or by a Post-office Order, sent to the President of the Council or the Secretary, which mode of remittance is specially pointed out, from being found the most convenient in conducting the business of the Society.

25th.—That all Papers and other communications be addressed to the Secretary or Secretaries, at Worcester, and forwarded carriage free.

* Seventeen Volumes of the "Transactions" have been published in 8vo., with numerous Plates, Wood-cuts, and Illustrations; and the *Provincial Medical, and Surgical Journal* is forwarded every alternate week by post on the evening of publication.

LECTURE
ON THE
DISEASES OF CHILDREN.

DELIVERED IN THE

Chatham Street School of Medicine, Manchester,

By DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Medicine at Vienna, etc.

LECTURE IX.

Emetics; Antacids and Roborants for the Stomach; Soothing Medicines; Tonics; Astringents for the Mucous Membranes; Nervine Stimulants; Tonics for the Spinal Nervous System; Narcotics.

EMETICS.

GENERALLY infants vomit easily, and frequently throw up a part of the undigested milk. The indication for an emetic is also not unfrequent, but in many instances difficult to determine, in consequence of want of subjective symptoms, which are only communicated by words. Frequent eructations, combined with anorexia, or irregular appetite, improper alvine dejections, and a puffed-up epigastrium, with a proportionally slight, or no alteration at all of the pulse, are the most frequent symptoms of indigestion, which serve as the indication for an emetic. Far more obscure and ambiguous in its phenomena is the bilious state, where, sometimes, neither eructation, nor the puffed state of the epigastrium, nor superabundant bilious matter in the evacuations, appear; and the head being heavy and hot, fever and moaning being present, it becomes sometimes very difficult to decide whether to direct our remedies to the affection of the head or of the liver. In similar cases I have frequently been able to unravel the intricacy by a careful investigation, by touch and percussion of the right hypochondrium, and by inspection of the urine, in which latter we frequently detect, by its darker colour, or by a yellow brown stain which it causes on the linen, the bilious state.

In this place we will content ourselves with these slight remarks, which will require a more accurate exposition when we shall have to speak of abdominal affections; it belongs, however, to our present purpose to observe that supposing there be a well-established indication for evacuation by emetic, very much will depend upon the mode in which we carry it into effect. Many an infant or child, when emaciated, weak, and nervous, has been severely damaged by emetic medicines. Amongst these the Antimonii Potass. Tart. is the most dangerous for them. I have seen its use followed by superpurgation and collapse, and by death. In tender infants and children, therefore, it will be the safest plan to produce vomiting by a large drink of warm water, after it tickling the fauces with our finger or the barb of a feather. The next suitable mild emetic is the following:—R. Rad. Ipecac., scr. j. To be infused in

five drachms of boiling water for a quarter of an hour, strain half an ounce, and add Oxym. Scill., oz. ss. One teaspoonful every ten minutes. If we want it stronger, we may add to the same one to two drachms of Vin. Antimon.

The strongest emetic is the simple solution of tartar emetic. For a child about two years old one grain to two ounces of distilled water, of which, in case we wish to act at the same time upon the alvine evacuations, we administer at first some doses of one teaspoonful every quarter of an hour, and then two teaspoonfuls every ten minutes, until the full effect comes on.

Hyperemesis may be checked by a half, one, or two drops of tincture of opium, followed by a little effervescent mixture; its over-purging effect by a hot infusion of camomile, with an appropriate dose of tincture of opium.

ANTACIDS AND ROBORANTS FOR THE STOMACH.

Magnesia, Carbonated and calcinated, are both frequently prescribed in children's practice against acidity of the stomach and dyspepsy. I find they seldom improve the digestion of little patients, and a quantity sufficient to absorb a common amount of acidity in the stomach will most likely derange this organ by its bulk. At any rate the doses as commonly prescribed are too large. In the first week after birth I regard this plan as improper; and for children from one to two months old, a single dose, to be repeated three or four times a day, ought not to exceed one grain or a grain and a half.

Rhubarb, in powder, I do not like to recommend in earliest infancy. About the third or fourth month a single dose, intended to act as a tonic, ought not to exceed a quarter of a grain. The following digestive powder may be recommended:—R. Magnes. Calcin., gr. xij.; Pulv. Rad. Rhei., Pulv. Semin. Foenic., utrq., gr. ij.; Pulv. Doveri., gr. j.; Sach. Alb., scr. j. Fiat. pulv. Divid. in part. æq. viij. This for children of about four or six months old (Dover's powder being added if there be great irritability of the bowels). I prefer, however, for tender children the following prescription:—R. Aquæ. Chamom., oz., j.; Aquæ. Menthæ., dr. ij.; Sodæ. Bicarb., scr. j.; Tinct. Rhei. Aquosæ., gtt., xij.; (Tinct. Opii., if necessary, gtt. ij.) One teaspoonful every three or four hours. In all similar cases I find the addition of syrups improper.

Frequently the indication in question is fulfilled the best by a suitable regulation of diet and the occasional use of a slight infusion of camomile, mint, or fennel seeds.

SOOTHING REMEDIES, TONICS, AND ASTRINGENTS
FOR THE MUCOUS MEMBRANES.

Radix Salep—mucilaginous and a little astringent—scarcely used in this country, is one of the most generally employed remedies on the continent, particularly in Germany, Italy, and Hungary, against the mucous diarrhoea of children, in powder as well as in decoction. A slight ebullition is enough to get the

whole dissolved. It is the most suitable vehicle for opium, in diarrhoea, and I must recommend it to you very warmly in children's practice.

Lichen Islandicus.—Much similar to the former, with the addition of its bitter extractive. It acts in the atonic bronchial catarrh just as favourably as salep in that of the intestines. An excellent preparation is got by evaporating a strong decoction of it, and exsiccating it slowly, so far as to be pulverised. This, in some Continental pharmacopœias is called *pulvis gelatinæ lichen-islandici*, and prescribed in quantities like gum-acaciae.

Tanninum.—The strongest vegetable astringent, which I prefer to colombo or cascarilla, because it acts in very small quantities, whilst the decoctions of the latter are not less disagreeable to infants and children, and besides that, too heavy in efficacious quantities; but even tannin I seldom employ for tender suckling children, and prefer to it—

Kino.—The powder of it, from a quarter to one grain three or four times a day, will prove efficacious in atonic catarrhal diarrhoea, if the case be a simple and manageable one.

I will now bring before you some of my formulæ of the above remedies:—*R. Rad. Salep., gr. viij.; Ebul. in q. s. Aq. usque ad solut. Dein infunde Radicis Ipecac., gr. iij. Post hor. 4. Colat., oz. j. Adde Tinct. Opii, gtt. j.—ij.; Syrup. Papav., dr. j.* For infants under one year old, every two or four hours, one teaspoonful against simple catarrhal diarrhoea.

R. Pulv. Rad. Salep. Subtiliss. Sach. Alb., utr., scr. j.—ij.; Pulv. Doveri, gr. j.—ij. Fiat pulv. Divide in part. æq. viij. For the same purpose. Each dose being administered with a spoonful of warm water.

To this formula, in highly atonic cases, we may add from two to three grains of pulverized kino or tannin.—*R. Pulv. Gelatinæ Lichen. Island. Sacch. Albi., utr., scr. j.—ij.; Pulv. Dover., gr. j.—ij. Fiat pulv. Dividi in part. æq., viij.*

Against bronchial catarrh, to be administered like the former, three or four times a day.

NERVINE STIMULANTS.

Some Aromatic Flowers, Herbs, and Seeds are prescribed in hot infusion, and are very useful against those irritations of the nerves, in particular, those belonging to the splanchni-spinal sphere, which, in the forms of spasms, so frequently infest young infants and children. Each dose ought to be prepared when needed. I can recommend the flowers of camomile, the herbs of mint and melissa, and the seeds of fennel and anise, most particularly in abdominal irritations and spasms, with flatuosity. The infusions ought to be given warm, from one to three spoonfuls for a simple dose. Allow me to draw your attention to one circumstance much deserving it. Camomile flowers are a common domestic medicine over the whole Continent. In Germany you will scarcely find a family, where there are young children, that does not keep it in the house. In England we find the contrary. Why? The simple reason is, that the soil and climate of this country is not favorable

to the development of the aromatic principle. I had not long arrived in England, when I observed that the fruit grows much larger than in Germany,—for example, strawberries—but is much less flavoury. A difference still greater you will perceive with aromatic herbs and flowers. Remember my words when you get into practice, and will have to attend families with children, do not neglect then to request a pharmaceutical chemist, to procure from Hamburgh the German camomile, which you will find highly useful in every-day instances in the slight but exceedingly frequent abdominal rearrangements of infants. If you compare the English flowers of camomile with the German, you will find the former of a very handsome white appearance, and three times larger than the German, and this latter unobscured and yellow brown; but the difference of the infusion will be this,—the English very bitter and little aromatic, and the German little bitter and strongly aromatic. With regard to the strength requisite for an infant one or two weeks after birth, it may be one teaspoonful of an infusion made of one scruple of flowers upon three ounces of hot water during ten minutes. For a child two years old, for example, you may give more at once of an infusion of the double quantity of flowers, infused during fifteen minutes. Adding to the dose of from one to four teaspoonsful, one-eighth to one-half drop of the tincture of opium, according to the age of the child; this will prove active enough in soothing the common dyspeptic irritations and abdominal pains of infants.

Camphor, powerfully stimulant to the vaso-motory nerves, is the unique of similar stimulants, of which I made use in the adynamic fevers of children, alone or combined with quinine. The single dose for the age of from two to four years seldom ought to exceed one-eighth to one quarter of a grain every four or six hours.

Liquor Ammoniacæ.—The strongest of this kind of stimulants, seldom admissible, and only in the highest degrees of torpid adynamia, from one to two drops, with a spoonful of an aromatic infusion.

TONICS FOR THE SPINAL-NERVOUS SYSTEM.

Salts of Quinine.—I have seldom met with their indication in earliest infancy, intermittents being rare at this period of life. Useful as it is, as a general tonic, in some forms of adynamic fevers, with great prostration of muscular power, we seldom find opportunity for its employment before the third year. Children take it with great aversion, and their stomach frequently disagrees with it. Very much depends, therefore, upon the mode of its prescription. The following formula I found to answer the best:—*R. Aquæ Menth Pip., dr. vj.; Quinin. Sulph., gr. ij.—iv.; Acid. Sulph., q. s. ad sol.; Syrup. Simpl., oz. j.* One teaspoonful every hour during remittance or intermittence, until its full effect.

In the highly adynamic stage of typhus, camphor may be combined with it, and in the case of great nervous hyperæsthesia with inactivity of the skin, we add

opium to both. Quinine is decidedly counterindicated by gastric, in particular by bilious, disorders.

I have tried, and recommended quinine to be further tried against spasmus laryngeus and whooping cough. In both cases essential conditions of its application are the pure nervous nature of the affection, and the vegetative weakness of the child; and a good state of the abdominal organs. The good effect, if any, will show itself already between twenty-four and forty-eight hours provided the doses are administered actively enough.

Nux Vomica.—Tonic for the locomotive innervation of the spinal cord. The salts of strychnine are too powerful to be properly adaptable for young children. Above the age of eight years, the dose of the sulphate of strychnine may be from 1-48th to 1-24th of a grain morning and evening. The most convenient preparation is the alcoholic extract of *nux vomica*, from 1-10th to half a grain twice a day, for children from three to ten years old.

According to my experience this remedy is mischievous in that kind of paralysis which is characterized by permanent tonic contracture of the flexors, and called by French authors "*contracture essentielle*." In some chronic and purely atonic diarrhoeas I found it useful; but it is difficult to determine beforehand which case will be favourable for it.

Iron.—The special tonic for the blood. I have frequently ascertained the state of chlorotic anæmia, even in young children, by the carotid murmur, connected with paleness and languor of their complexions. Good preparations are the saccharo-carbonate and citrate of iron. For children about two years old from one to two grains for a single dose of the former, and one-eighth to a quarter of a grain of the latter.

I beg to recommend to you a preparation of iron, the finest which I know, possessing, besides its chemical action upon the blood, a strong nervine quality. This preparation is known in Germany under the name of *tinctura nervino-tonica Bestusheft*, while its proper pharmacological name is *spiritus sulphurico-athereus muriatico-ferratus*. A chemist will be able to prepare it in the following way:—Take one part of the liquor ferri sesquichlor., and two parts of sulphuric æther, let it be mixed for a quarter of an hour, then let it stand for a while, and afterwards take away the æther which occupies the surface of the liquid. This is to be mixed with twice its weight of rectified spirit of wine. Let this mixture stand exposed to light (if possible to the sun) for several days, until the liquid becomes more discoloured. Conserve it afterwards in a hermetically-closed bottle.

This preparation is to be considered as a solution of iron in liquor Hoffmanni, of which it possesses the nervine qualities. Its true indication, therefore, is chlorosis or anæmia, connected with nervousness. The doses for children are from one to two drops twice a day. This preparation is also an excellent nervino-tonica for delicate females.

NARCOTICS.

Hyoscyamus, *aconitum*, *belladonna*, *aqua lauro-cerasi*—as soothing remedies against irritation and

pain—frequently employed by practitioners, seem to me, after a strict comparative trial, to be scarcely trustworthy.

Opium is the only remedy of the kind powerful and of utmost utility in children's practice; but we must be aware of its counter-indications, and, if indicated, know how to administer it. Essential counter-indications are,—acute fever, with an active character; typhus, connected with nervous torpor; active and passive congestion of the brain; saburral, or bilious gastric disorder. Moreover, it is necessary to bear in mind that tender and exhausted children are easily narcotised to a dangerous degree by doses moderate in proportion to their age.

It is important to wait after each dose of opium at least three or four hours before the administration of the next, in order to enable ourselves to watch the effects, and stop in time, as soon as narcotism shows itself.

Moderate narcotism, if the remedy were truly indicated, will go off without bad consequences. If, however, narcotism should increase more than five hours after the last dose, we apply large cold fomentos to the head, a mustard poultice to the neck, and a purging injection. If these means show no advantage in about an hour, we apply some leeches to the temples, and administer from one half to two teaspoonfuls of recently roasted and infused coffee, to which, in cases with much abatement and exhaustion, we may add from a quarter to one drop of liquor ammoniæ; this may be repeated, according to the nature of the case, once or several times, at an interval of half an hour or an hour.

To find out the proper dose for the case is very difficult; not only the age and constitution, but many imperceptible peculiarities and dispositions, besides the nature of the disease itself, make numerous modifications in the effects of this powerful remedy. I have prescribed of opium, as far as possible, effective doses in many thousands of cases, in particular of irritations of the bronchial and intestinal mucous membranes, and should think the following gradation may be regarded as safely applicable at first in the large amount of ordinary cases, and to be afterwards increased if necessary:—

				Grain.
From the 1st to the 3rd week,	middle doses			1-120th
“ 3rd “ 6th “	“	“	“	1-100th
“ 6th “ 8th “	“	“	“	1-70th
“ 2nd “ 4th month	“	“	“	1-40th

After these tender ages the doses must not increase in that proportion, because the development of the organism does no more go on with that rapidity. Thus the full dose for a child two years old may be about 1-20th of a grain, and for a child four years old 1-10th of a grain.

Pulv. Doveri.—That preparation of which I make general use in children's practice contains in ten grains one grain of opium. Of the simple tincture of opium fifteen drops are equivalent to one grain of opium in substance.

It must be earnestly remarked in this place that *the action of opium by injection*,—that is to say, by the

way of intestinal absorption, is much less constant and measureable than that by the stomach. I have ascertained this by a large number of observations. The state of the mucous membrane of the colon is subject to much more variations than that of the mucous membrane of the stomach; and, besides that, much will depend if, and how long, the injection remains within the bowels, or how much of it has been voided after a certain time. Thus, in two children of a good constitution, both two years old, the same dose given by injection may produce very different results, according to the length of time during which the liquid is retained within the rectum; and for the same reason in the one three drops of the tincture will produce narcotism, whilst in another the double quantity will remain without effect upon the brain. If we can suppose that the injection will be absorbed, we may administer only the double of what we would give by the mouth.

Digitalis, frequently employed as an antiphlogistic, in particular against acute affections of the brain, I have been fully satisfied does not answer that indication. As a diuretic, it must be postponed to many other remedies of the kind; this action of it being particularly inconstant in children. The unique real indication of *digitalis* is the nervous hyperæthiis of the heart, unconnected with inflammation or aneurism. The best mode of administering it is by two doses daily, at the interval of twelve hours. The single doses may be for the third year a quarter of a grain, for the fifth one-third of a grain, and for the eighth year half a grain, which can be considerably augmented. Commonly, too small doses are prescribed.

CASE OF STRANGULATION OF THREE FEET OF THE JEJUNUM,

BY A RENT IN THE MESENTERY, PRESENTING NO SYMPTOMS OF THE DISEASE FOR SEVERAL HOURS, AND THEN TERMINATING VERY RAPIDLY.

By CHARLES BAILEY, Esq., CHIPPENHAM.

Read at the Quarterly Meeting of the Bath and Bristol Branch, March 25, 1852.

HENRY TAYLER, aged 25, was on the 13th of March, 1852, in perfect health; in the evening of that day, after partaking of a hearty supper, he was returning home about a quarter of a mile distance, when at the half way of his return he fell over some large stones which had been carelessly left on the foot-path; he got up, did not feel much hurt, went into an adjoining house, and partook of some warm beer, and smoked a pipe of tobacco; after sitting about half an hour went home to bed, did not complain, but slept soundly till six o'clock; came to his employment a little before eight. Feeling some uneasiness about the bowels, he was induced to seek their relief; this was effected, and urine was also voided. Directly upon this the pain became severe, and he vomited several times; the ejected contents had not undergone digestion, as the food of the last meal of the

preceding day was unaltered. Frequent rigors, cramp, thread-like pulse, cold extremities, and leadened countenance. When I was first apprized of his illness I found that thirty drops of the tincture of opium had been given in a little warm brandy and water, and was rejected. Being ignorant of the fall of the previous night, and conceiving he was labouring under spasmodic colic, I gave him a pill, consisting of two grains of opium and two of calomel; this remained, but still there was no abatement of symptoms. He then related the circumstance of his fall, but said he was sure that would not have anything to do with his present painful condition. I again examined him, could find no tenderness, but he complained of a fulness and tension. Being put into bed, after warm appliances to the abdomen and feet, with doses of the compound spirits of æther and small quantities of tincture of opium, a little reaction took place, yet no abatement of pain, therefore, listening to the entreaties of the poor fellow to do more for him, I reluctantly took away ten or twelve ounces of blood, and he expressed himself relieved. Small quantities of fluid now remained on the stomach. Another dose of calomel only was given, and shortly after one ounce of castor oil; this remained, without any more sickness, which led me to hope the result would have been different, but in about three hours he breathed his last, having endured seven hours severe pain.

The following day my young friend, Dr. W. Colborne, examined the body. No external appearance of injury. On opening the abdomen, more than a pint and a half of bloody serum was found; intestines much inflated; on placing aside the omentum and colon, there was seen a considerable portion (three feet) of the jejunum in a state of mortification, with much discoloration of the connected parts. By carefully carrying on the examination, it was discovered that the mortified part of the jejunum was strangulated, or rather had been so, in a wound or rent of the fold of the mesentery, through which the intestine had fallen, and its functions been destroyed. No injury had been inflicted on any other organs of the abdomen. Other parts of the body not examined.

Hospital Reports.

MANCHESTER ROYAL INFIRMARY.

CASES

Reported under the terms proposed by the Association.
By MEDICUS.

Fungus Hematodes after Fracture.

GRACE FAULKNER, aged 39, factory operative, Duckinfield, was admitted into the Manchester Royal Infirmary, under Mr. Wilson, October 10, 1850. She states that on the 16th of August, 1850, she fell down, her arm twisted under her, and fractured both radius

and ulnar. She applied to a quack doctor, who said it was "out," not broken, and put on a plaster and bandages. The first dressing remained on a week, during this time it swelled considerably, and was at times exceedingly painful. On the seventh day the dressings were removed and similar ones substituted, but put on more loosely. The pain continued, and when these were removed, a small tumour, about the size of a marble, was perceived; to this some embrocation was used, the pain, however, continued, and after some time, proper medical advice was sought. The true state of the case, as far as the fracture was concerned, was then discovered, and various means used, but the tumour continued to increase, the pain persisted, and was so severe as to prevent her sleeping. When admitted, the tumour was about the size of an orange, of a livid hue, soft and fluctuating in parts, the veins around it are much enlarged, and the hand slightly oedematous; the pulse at the wrist much the same as on the other side; general health tolerably good.—Ordered Cataplasma Lini and opiate at bed-time.

20th.—At a consultation to-day it was agreed to puncture the tumour, which is rather larger; general opinion that it is fungus hæmatodes.

21st.—It was punctured to-day, and a quantity of bloody serum poured out; there was some bleeding afterwards, which was stopped by pressure.—Continue remedies.

27th.—Tumour much increased in size; fungous granulations project from where the puncture was made; it is much darker in colour, and there is evident fluctuation in several parts; her health is suffering, apparently from the air of the hospital.—Some medicine was ordered, and she was sent into the country.

December 11th.—She was readmitted much improved in health; tumour rather larger; she is a little feverish. Ordered a saline mixture, with morphia. She refused any operation to be performed on it, and after a trial of various remedies, her health again suffering, she was sent into the country on the 6th January, 1851.

January 27th.—Readmitted; tumour much enlarged, dark in colour; skin over it much stretched and glazed; health much improved.

February 6th.—At a consultation it was agreed to make an incision into the tumour, and then, if necessary, remove the arm.

7th.—The patient being placed under the influence of chloroform, an incision was made into the tumour, and, as there could be no doubt as to its nature, it was at once removed by amputating the arm above the elbow; eight or nine ligatures were applied as the arteries were much enlarged, and the wound dressed temporarily with wet lint. At night, no hæmorrhage having occurred, it was dressed, no sutures being used. An opiate at bed-time. Two or three days after the operation, she had an attack of feverishness, which was relieved by salines and an antimonial. At intervals she had attacks of dyspnoea, which were immediately and singularly relieved by opium.

March 5th.—She has continued to progress without

any symptom worthy of note; a small abscess has formed in the stump, which has been opened.

24th.—The abscess has healed rapidly, and she was discharged cured to-day.

ROBERT RAND, aged 13, weaver, Heywood, was admitted in the Manchester Royal Infirmary, under Mr. Ransome, February 10, 1851. He states that sixteen weeks previous to his admission he was knocked down, and his thigh fractured four inches above the knee; it was set by a surgeon the next day; it was excessively painful for a week, at the termination of which period the medical attendant readjusted the apparatus, leaving it on this occasion for a fortnight. At the end of eight weeks from the accident happening, he removed the splints, and merely applied a plaster and bandages. The boy states that during the time the splints were applied, he had great pain, and there was considerable swelling. The medical attendant continued to apply bandages and plasters once a fortnight up to the time of the boy coming to the hospital. At the present time there is a tumour of livid hue, which has dull aching pain in it, extending from the knee to within three inches of Poupart's ligament; large veins run over it, and fluctuation is distinct in some parts; the glands in the groin are much enlarged, and rather tender; he sleeps badly, and his general health is bad; he is seized at times with dyspnoea, which, like the former case, is greatly relieved by opium.

21st.—The tumour has ulcerated in one or two places, and discharges bloody serous fluid; his appetite is failing, and his health giving way fast; the glands are becoming more implicated.

March 6th.—At a consultation it was agreed that an operation was inadmissible; the tumour increased, and glands are worse.

10th.—He was discharged incurable, the principal medicines which he had taken being opiates.

The points of interest in these cases I take to be their evident origin in the injury, the age of the parties, and the singular attacks of dyspnoea from which both suffered.

Gangrene of the Leg from Aneurism of the Aorta.

WILLIAM GREEN, aged 43, labourer, Manchester, was admitted into the Infirmary, January 23, 1852. He states that he has always had good health until thirteen weeks before admission, when he took cold and had inflammation of the lungs, from which he recovered. On the 21st of January, whilst going to his work, he suddenly felt a severe pain in the right knee, which quickly extended down the leg, and it became numb and cold. He went home, sat by the fire, and got some one to rub the leg; whilst sitting by the fire, so imperfect was sensation, that he allowed the limb to be burnt rather severely, and was not aware of the circumstance till it was pointed out to him.

At the time of his admission the leg was red, oedematous, raised into large blisters, and traversed by red

lines, extending as high as the knee. On the calf of the leg, where he suffered it to be burnt, there is a slough about four inches square, and another on the foot, of smaller extent. He has no sensation as far as the knee, but he complains of pain above on pressure nearly to the hip. Pulse full, quick, and irregular; has some cough and pain in the chest; perfectly sensible and answers questions rationally.—Ordered one grain of opium every three hours, poultice to leg, also a febrifuge mixture; he was put on extra diet, and a full dose of opium given at bed-time.

24th.—He was delirious during the night; inflammation active, and seems extending up the leg; bowels open; pulse quick, and irregular.

25th.—He is much worse; inflammation has extended up the leg, and he has no sensation in the limb above the knee; thigh painful on pressure, red lines extending upwards; pulse quick and weak.—Continue remedies. Ordered Vin. Rubri, oz. vj., daily.

26th.—He continues much the same.

27th.—He is worse; has been very delirious; face sunk; abdomen tympanitic; pulse weaker; tongue dry.—Ordered a mixture of bark, ammonia, and opium; beef-tea *ad libitum*.

28th.—A somewhat indistinct line of demarcation begins to be perceptible below the knee; he is exceedingly restless and answers questions incoherently; pulse weaker and irregular.—Continue remedies.

29th.—He is evidently sinking; limb much the same.

30th.—He continued to get worse; the line of demarcation is more distinct; he has delirium, hiccup, vomiting, and is sinking rapidly. He died about three o'clock, P.M.

Post-mortem twenty hours after death.—Lungs inflamed, and very adherent; an aneurism of the arch of the aorta about the size of an orange, containing coagula, which were very loose; left ventricle was enlarged; abdominal viscera healthy; limb gangrenous to the knee. On laying open the large vessels a large clot of blood was found blocking up the popliteal artery, also another in the external circumflex artery, and one in the superficial external circumflexa ilei. Rest of the viscera healthy.

In this case there is no doubt that a portion of the loose coagulum from the aneurism of the aorta had been carried on with the current of blood, and being arrested at the spots above stated, cut off the circulation completely from the lower part of the limb.

Carbuncle and Saccharine Urine.

JOHN BROADBENT, aged 66, of Manchester, packer, was admitted as a patient of the Manchester Royal Infirmary December 12th, 1851. At this time he presented, on examination, a large carbuncle on the back of the neck; it had a quaggy feel, and when pressed pus exuded from numerous cribriform openings. His tongue was moderately clean, and his pulse weak. A crucial incision was made into the tumour, poultices subsequently applied, and a mixture ordered, containing

bark, ammonia, and opium. He stated, on the question being put to him, that he thought the quantity of urine increased; it was ordered to be measured, and a portion reserved for testing the following day. The urine measured five pints, specific gravity 1.031. Tested by being boiled with liquor potassæ, it produced the deep colour so characteristic of diabetic sugar. Boiled with sulphate of copper, and excess of potass, it yielded immediately the red oxide. A portion was put on one side for about forty-eight hours, and when examined by the microscope showed an abundance of torula.

The subsequent treatment was conducted on the ordinary principles of surgery. Tonics were given, with a generous diet and stimulants. Stimulating applications were applied to the wound. The patient recovered rapidly, and in a few days not a trace of sugar could be discovered in the urine. The sugar remained for sixteen days after he came under treatment, in variable quantity, and continued steadily diminishing, as follows:—

Dec. 17.	Urine four pints and a half.	Sp. grav.	1.031.
" 21.	" four pints	"	1.030.
" 25.	" four pints	"	1.026.
" 29.	" three pints and a half.	"	1.023. Slight indication.
" 31.	" less than three pints.	"	1.024. No sugar.

JOHN OWEN, aged 62, of Manchester, green-grocer, was admitted a patient of the Manchester Royal Infirmary November 21st, 1851. At the time of his application he presented a large carbuncle at the back of the neck. He was exceedingly ill; bowels confined; pulse weak and rapid. The tumour presented the usual venous hue and cribriform openings; it was freely opened. Ordered a stimulant poultice. A full dose of calomel given, the bowels well opened, and then a tonic mixture of bark, ammonia, and opium administered. The urine was ordered to be measured, and kept for examination.

The man is improved this morning; the pulse has improved in quality, and the wound looks as well as could be expected; he has had some delirium in the night; urine measured five pints and a half, specific gravity 1.034; the tests mentioned before were applied, and the presence of sugar easily demonstrated. There was nothing after this in the case particularly worthy of notice; the case improved rapidly under good diet, stimulants, and tonics, and the sugar disappeared from the urine in eight days. A trace was again to be found on the tenth day, after which no more could be discovered.

These cases are of interest as showing the presence of sugar, but a comparatively short time has elapsed since it was first pointed out, and it has been repeatedly questioned. In these cases there could be no doubt as to the existence of the sugar; it was freely poured out, easily found, rapidly diminished under treatment, and ultimately disappeared altogether.

Provincial Medical & Surgical Journal.

WEDNESDAY, APRIL 14, 1852.

WE have received numerous inquiries relative to the conditions of the Prizes for Hospital Reports offered by the Association, and we think the subject of so much importance as to require some observations from us.

Without enumerating the various questions asked of us, we may make the following statement, which will explain all the points touched upon by our various correspondents; and first, then, though by the terms of the proposed prize, House-Surgeons and Pupils are specially mentioned, yet it was never intended to be confined to them, but rather, on the contrary, extended to them as a boon, even though not yet members of the profession, or of the Association. We repeat, therefore, that the prizes are offered to all those who are either members of the profession practising in the provinces, or are pupils or resident officers in a provincial hospital, and that the cases should be *recent*, though not confined to the years 1851-52.

We are extremely glad to find so many and such interesting cases sent to us for competition, and we yet hope to receive even more valuable records of provincial practice. We shall, we hope, be able to find room for their insertion in the *Journal*; but we again recommend condensation, not only as convenient to us and to our readers, but as an important element of success in the object which we conclude all have before them.

OUR respected associate Mr. KING seems to consider, when writing the communication inserted in our last number, that the Worcester Council have only to issue their mandate, and the difficulties attending on the question of Medical Reform will disappear like a house built of cards. We assure that gentleman that if he supposes that either Sir J. GRAHAM or Sir G. GREY could be easily persuaded to take charge of the Bill, he is somewhat mistaken; but still, granting that difficulty overcome, there is the still greater one of finding the funds necessary for carrying a private Bill through the House of Commons, for we cannot suppose that Mr. KING would expect the Worcester Council to have so much magical power as to be able to persuade any

private member of the House of Commons to put his hand in his pocket to the tune of £500 or £600. Yet all this is necessary to such a result; Mr. KING's views must, therefore, be considered as perfectly Utopian.

All that the Worcester Council or the other promoters of the Bill can do, our readers may rest assured will be done. The Bill will be fully matured, the opposing interests, as far as possible conciliated,—having, however, due regard to the principles invariably maintained by the Association, and we hope the Secretary of State for the Home Department may be induced to take the measure under his care before the next Session of Parliament. In the meantime the annual meeting will be held at Oxford, and it may then be considered (if it should be thought advisable so to do) whether the Association should set apart any sufficiently large sum for the furtherance of this scheme of Medical Reform. We are by no means sure that this would be considered by the majority of the Association a legitimate object upon which to disburse the funds at their disposal. Many would think that such an expenditure would be utterly useless, and others that it might be better employed upon objects of science or art. At all events it cannot be considered that the Worcester Council are lukewarm in the cause if they decline to exceed their powers, according to Mr. KING's proposal, by at once proceeding with the Bill at their own risk and individual peril.

Proceedings of Societies.

BATH AND BRISTOL BRANCH.

THE Quarterly Meeting of the BATH AND BRISTOL BRANCH OF THE ASSOCIATION was held at the York House, on March 25th, when there were present—Mr. Norman, in the Chair; Dr. Swayne, Messrs. Colthurst, Estlin, Lancaster, Leonard, Mayor, Morgan, Neild, and Wilson, of Bristol; Drs. Davies, Hodges, and Tunstall, Messrs. J. Barrett, Bartrum, Church, Cox, Hensley, King, Mason, and Stone, of Bath; Messrs. Bailey and Colborne, of Chippenham; Crang, of Timsbury; Edwards, of Batheaston; Flower, of Chilcompton; and Vicary, of Warminster.

THE PRESIDENT, on opening the meeting, expressed his opinion that, for the benefit of all parties who had papers to read or observations to make at these gatherings, it was essential that the chairman should be empowered to call upon all persons occupying the attention of the meeting to confine themselves within such limits

of time as the Chairman might think discreet, who should not allow any one to speak twice upon the same subject, except the gentleman introducing it, to reply to any observations elicited in the discussion.

The minutes of the last meeting were then read and passed.

A case was then read by Mr. BAILEY, detailing the strangulation of a portion of the jejunum, three feet long, by a rent in the mesentery, caused probably by a slight fall, in which no symptoms of the injury had been present for several hours after the probable time of the occurrence of the accident. [This case is published at page 188.]

Mr. NIELD then detailed his experience in the application of solutions of nitrate of silver to the glottis, in various affections of that organ. The forms of disease in which he had successfully used it, were laryngeal irritation, cases resembling croup, in some cases of dyspnoea dependent on irritability of the upper part of the trachea, and chronic bronchitis arising from a similar cause; also in two cases where the mucous membrane of the posterior nares was thickened and diseased. He adverted to the varying action of the nitrate upon the mucous membrane according to its condition and the strength of the solution. He drew the attention of the meeting to the necessity of various sizes and shapes of the instrument, and detailed how to distinguish whether the probang had entered the glottis, or gone down the œsophagus. Having himself derived much benefit from it he confidently recommended its use in appropriate cases. [This paper to be published in the *Journal*.]

Dr. DAVIES had long been sceptical of the advantages said to be derived from the topical application of this remedy; but recent observation, and the extended experience of several independent observers, Dr. Hastings, Dr. Green, Dr. Bennett, and now of Mr. Nield, had convinced him that occasionally it was useful, especially in such cases as had been detailed. He had now provided himself with the requisite instruments, and hoped, on some future occasion, to be able to lay before the Association the results of his experience.

Mr. WILSON drew the attention of the meeting to the anomalous position in which at present medical men stood towards many of the Life Insurance Companies. He wished to know what was the usual practice of members of the Association, and whether they would pledge themselves not to sign certificates without a fee being paid by the office requesting the answer. He always refused to sign certificates, except the office paid the fee for the inquiry, the ordinary medical attendant being the only person who, in doubtful cases, could give trustworthy information. In unfavourable cases the office assuredly is the party who ought to pay the fee, for how would the patient like to pay for an inquiry whereby he had been prevented effecting an insurance.

Mr. NORMAN felt that there was much difficulty in the whole question. Assuredly the medical opinion ought to be paid for, as on it often depended the eligibility of the life. In the greater number of the offices the

facts known only to the ordinary attendant of the applicant was part of the preliminary information required before the office would entertain the proposal, the office implying that he would furnish it for their use.

Dr. DAVIES could not but think that the office was the party who ought to pay for the medical opinion, as it thereby is specially benefitted. Take, for example, a case of epilepsy or albuminuria. Could the medical referee of the office, who probably knew nothing of the previous history of the case, ascertain the existence of such diseases? Certainly not. Unless strongly marked the only person competent to give a history of such cases was the ordinary attendant. He felt convinced that if the medical profession were unanimous in the matter, before long all the offices would yield, as many others had already done.

Mr. STONE had always acted on this view. The questions came from the office; however, some might now cunningly make the applicant sign the request for the information. The questions were private, became the property of the office, and might by it be brought into court. On these grounds, as well as those urged by previous speakers, a fee should be paid for the opinion, and should be paid *through* the office, at any rate. In some cases he had refused to answer the questions without a fee; and consequently he had known several cases insured without difficulty whose lives were very bad indeed, and so he had been saved the odium of causing their rejection. By his refusal to give the information without the fee, he had several times caused patients to insure in fee-paying offices. By medical men acting thus, gradually all the offices would come to a sense of their own interest, as well as do justice to the medical profession.

Dr. TUNSTALL rejoiced that the subject had been brought before the Association. He mentioned the following case under his own observation:—A man, whose health had been so bad that his friends did not suppose he would live twelve months, applied to an office whose referee passed him, his ordinary attendant not having been applied to; the life was accepted without such inquiry, and within six months the party died of the disease he had been labouring under.

Mr. NIELD, to exemplify how medical men would evade giving gratuitously an unfavourable opinion, mentioned the following circumstance, which he believed was not infrequent:—The usual opinion was asked of one who, knowing the ineligibility of the life, recommended his patient to apply to another medical man who occasionally had seen him, but did not know so much of his condition. On his report the life was immediately taken, which otherwise it would not have been. He suggested that a resolution be drawn up, and forwarded to all the life offices.

The subject being of a nature not usually entertained at these quarterly meetings, it was eventually arranged that it should form part of the proceedings at the annual meeting in June.

Mr. EDWARDS exhibited a new truss, with elastic belt, for infantile umbilical hernia, which he had found most convenient and useful.

EAST KENT & CANTERBURY MEDICAL SOCIETY.

SESSION 1851.

Pathological specimens relating to the following cases were exhibited :—

Cyst in the Brain filled with Pus, the surrounding Structure being softened.—By DR. LOCHÉE.

A. R., aged 20, fell suddenly from his chair, immediately after dinner, Oct. 16, 1849. The waiter of the hotel where he was staying heard him fall, and entering the room found him insensible. He remained so for three or four minutes, with slight convulsions, but had quite recovered his faculties by the time his medical friend, who lived close by, had arrived. This gentleman remained with him in the room, and was present when the patient, four hours afterwards, had a second seizure, lasting about the same time, and which had all the characters of epilepsy. He recovered from this fit also, but grew flushed, talkative, and restless, though not incoherent. He seemed to those about him to be going on favourably, with no recurrence of the fits until the 23rd, when the left arm was observed to be partially paralyzed, and he looked flushed, complained of slight headache, and was evidently heavy and oppressed. He was bled from the arm to eight ounces but as that led to no amelioration of his symptoms, Dr. Lochée was requested to see him on the morning of the 24th of October. His state then was as follows :—His general appearance and expression were very similar to what is seen in patients when pure inflammatory fever is passing into the typhoid form, the symptoms referable to the brain being more those of congestion and adynamia, than of active mischief. He was stolid and dull in his manner, though conscious; when disturbed and roused he generally answered questions correctly, but not always; he made no complaint, but on the contrary said there was nothing the matter with him; then for some minutes he would take no notice of anything that was done or said. His breathing was slow and rather laborious. The pupils were moveable under strong light, but rather dilated, or spontaneously flickering from one state to the other. The left arm was quite palsied, with involuntary twitching and starting of the tendons at the wrists. The bowels had not acted for twelve hours. The tongue was covered with a yellow fur. The pulse was 90, wavering and compressible. The urine had passed in tolerable quantities two hours before the visit.

The history of the case was interesting, and the unnatural excitement under which he had long laboured, and which, though remarked by his friends, did not give rise to any alarm, was ultimately shown to be produced by a tangible disease of the brain, which had kept up constant irritation. He was naturally very talented, extremely quick, with a wonderfully retentive memory. His conversational powers were of a brilliant kind, so much so as to make him eagerly sought after in society to enliven the dulness of others. This caused him to lead

rather an irregular life, one of constant mental strain and excitement; he also lived freely, more, however, on account of good fellowship, than because he had any pleasure in doing so, for when alone, though he liked to see his table loaded with various wines and viands, he seldom touched any of them. Twelve months before his attack his admiring friends thought him more brilliant and eccentric than ever. He was the life and soul of all their festive meetings. His imaginative faculties, always rich, became now exalted, so much so, as to make him do things which seemed strange even in him. He had the grandest ideas upon every subject; he would have nothing served to him except upon silver, profuse expenditure characterised everything he did. He read nothing but poetry of the most impassioned kind, and used to astonish his friends by repeating whole pages to them with much emphasis and gesticulation. In short, he could do nothing in moderation—if he had to talk, he would sing; and if required to walk, he would be more likely to dance. Such was his history up to the time of his seizure.

Leeches and blisters to the head, with half-grain doses of calomel, formed the essential part of the treatment. He rallied for two days under this treatment, and then fell again into his former state. He was now visited by a physician from London, a friend of the family, who pronounced the patient to be suffering from disease of the kidneys, and prescribed accordingly. In twenty-four hours afterwards, however, the symptoms were so manifestly aggravated that the former plan of treatment was resumed, and for a day or two the patient rallied again. The stupor and palsy left him, his mental faculties returned, and he seemed mending, when on November the 12th, he again became flushed, excited, and talkative, which state ran gradually into one of active delirium, terminating in deep coma, that endured for six hours before his death on the 14th of November.

Post-mortem examination.—A cyst, which was full of thick pus, was found in the left hemisphere of the brain, projecting partially into the left lateral ventricle, which cavity also contained about four ounces of greenish pus. The substance of the brain, for about half an inch round the cyst, was disorganised and softened, so as to be almost pulpy. There was no sign of any active inflammation anywhere. The kidneys were specially examined, but they were found to be healthy.

Hydatid in the Lung, accidentally discovered in a Patient who had died in Puerperal Convulsions.—By MR. G. RIGDEN.

This was an acephalocyst about the size of a pullet's egg, which was situated in the anterior and upper part of the lower lobe of the left lung. The tissue of the lung which surrounded the cyst in which it was enclosed, was quite natural. After it had been removed for a day or two, owing to the transparency of its wall, an inner membrane, thickly studded with minute and opaque spots, could be seen floating in the contained fluid, at a point where it had become detached from the outer lining.

The particulars of the case, which present some interesting points in relation to puerperal convulsions, are as follows:—

H. B., aged 40, was attended by a midwife in her confinement with her eighth child, and died from puerperal convulsions, two hours after delivery, January 31, 1851. She had been married eighteen years, and was of a very reserved disposition. Her father had died in a lunatic asylum; a brother had destroyed himself; and her twin-sister had suffered for a very long time from constant pains in her head. She herself had enjoyed good health until eight years since, when she was confined with her fifth child, and soon afterwards began to suffer pains in her head, for which she was admitted into the Canterbury Hospital. She was not relieved by the treatment employed, and after her discharge, she gradually became worse, and about a month afterwards attempted suicide, twice repeating the attempt in the course of three weeks. She was then placed in the Bethlem Hospital, London, where she remained ten months, and was discharged much improved. She continued so until her sixth confinement, after which, her head again became troublesome, but not to such a degree as to prevent her from attending to her family duties. She subsequently bore a seventh child, and had a good recovery. She was not attended by any medical man from the period when she left the asylum, until the 4th of May, 1850, when she became a patient of the Canterbury Dispensary, for paralysis of the left arm, which had attacked her suddenly on the previous day. She was discharged September 24, having recovered the perfect use of her limb. About six weeks before her death, she had cough and difficulty of breathing, which subsided without medical aid, but returned, though not violently, about a week before she died.

Post-mortem examination thirty-six hours after death.—The scalp separated readily, and was not congested. The bones of the portion of the skull removed, were thickened and dense, the diploe being absent; the arch of its internal surface was considerably flattened on its sides by bony deposit. The dura mater adhered firmly to the skull. The arachnoid covering the brain presented many opacities, but was not vascular; the tissue beneath was infiltrated with serum, so that in some parts the convolutions of the brain could not be seen through it. The pia mater separated readily from the convolutions, and presented a remarkably congested appearance, every fold that dipped into a sulcus having its vessels enlarged, tortuous, and filled with dark blood, and their arrangement being such as to give the appearance of a fine fringe. The convolutions of the brain were narrow, and very convex. The red points that appeared in the sections of the brain were large, and more numerous than usual. The substance of the brain was firm, and was minutely examined, but no remains of any old or recent effusion could be found. The ventricles contained rather more than their usual quantity of fluid. The upper, middle, and part of the lower lobe of the right lung, for the depth of three-quarters of an inch along their anterior surface, were in

a state of solidification from red hepatization. The uterus was firmly contracted, and occupied the entire pelvis. A thin coagulum marked the surface to which the placenta had been attached. Several veins were noticed projecting through the surface of the coagulum, and appeared to be twisted on themselves.

Cyst in the Cerebellum.—By MR. JAMES REID.

A sketch in water colours, exhibiting the appearance of the part in its recent condition, was also placed before the meeting.

The principal facts of the case were these:—A boy of 15 years of age became gradually affected with amaurosis, accompanied by severe pains in the head, which continued for two years, when he died, having suffered irregular general convulsions for three months, and having become very much emaciated. Although amaurosis was the earliest symptom noticed, so that, with the subsequent progress of the case, it warranted the conclusion before death that the existing lesion involved the optic nerve in some part of its course or origin; yet both the nerve itself, and the parts said to be concerned in the sense of vision, were found, on examination, to be perfectly healthy, and the disease to be situated in a part not acknowledged to have immediate connection with that sense. The details of this case, together with some remarks upon it, have been published in the forty-eighth volume of the *Medical Gazette*.

Hydatids in the Brain.—By MR. G. RIGDEN.

This specimen exhibited thirty hydatids, or acephalocysts in various stages of development and decay, contained in one pouch. The size of the entire cysts varied from that of a pea to that of a pigeon's egg. The collapsed or degenerated cysts were larger, and had their walls thickened; some of them contained a white, putty-like matter, of the consistence of thick cream; the largest of these, if distended, would have equalled the size of a hen's egg; its wall was the eighth of an inch thick, and its inner surface was corrugated.

The subject of this foregoing disease was a boy, aged 7 years, who became a patient of the Canterbury Dispensary, August 8, 1850, with paralysis of the left upper extremity, having the complete use of his other limbs. At this time he had no headache or other symptoms indicating cerebral disease. The affection of the arm resembled paralysis from the poison of lead; he was able with difficulty to raise the arm to the head, and sensation was not impaired. The mother stated that the child was naturally irritable, but she had not noticed anything wrong until two weeks previously, when the power of moving the left arm became affected. The pupils were natural. He was treated with mercurials, salines, and electro-galvanism, without benefit.

December 20, 1850.—He was attacked with epileptic convulsions, which continued at intervals for several days, and then ceased, the arm becoming gradually weaker.

April 25th, 1851.—The fits returned and continued

to recur, with slight intermission, until his death, which took place April 29, 1851.

Post-mortem examination.—The head only was examined. The skull was thin, and at its uppermost part was diaphanous. The dura mater was rather transparent; the surfaces of the arachnoid were less lubricated than usual, appearing almost dry and sticking slightly together. The convolutions of the brain were generally slightly flattened, but more so over the middle of the right hemisphere. On opening the lateral ventricles, the right corpus striatum was seen to project unusually, and when touched it gave way, an hydatid cyst issuing through the opening. The sac containing the hydatids occupied the middle and greater part of the anterior portion of the right hemisphere. The thalamus opticus was reduced to a mere layer, covering the sac, and was somewhat softened.

FRANCE.

Epithelial Cancer, or Cancroid.

Among the "*Memoires de la Société de Chirurgie de Paris*," is one by M. Lebert "On Cancer and Cancroid of the Skin." His deductions respecting the latter disease we give in the following *resumé*:—

Epithelial Cancer sometimes originates in a small warty tumour, at others in a superficial crack, and is not painful at its commencement. The warty tumour may reach the size of a nut without ulcerating. In the second period, or that of development, a certain amount of inflammatory hyperæmia occurs, which soon induces pain and ulceration. The character of the ulceration varies; on the face it generally excavates, while on the genital organs it creeps onward irregularly, accompanied by hypertrophy of the base, giving rise to warty excrescences. The mean duration of cancroid is about six years and a half; but this varies with the region implicated, the duration being shortest when seated on the lip. Sex has little influence on its development. In sixty-one cases there were thirty-one men and thirty women. The site, however, varies in frequency in the two sexes; in men the lip is most frequently the part assailed, in women less so than other regions of the face. The genital organs are equally liable to it in both sexes.

The causes of cancroid are little known. Phimosis seems to favour its occurrence on the penis; and the use of short pipes has been thought to cause its appearance on the lower lip. Cancroid may be unhesitatingly said to be a curable affection in certain instances; but it is so frequently the reverse that the prognosis must always be exceedingly doubtful.

The treatment of cancroid must be chiefly local. Early operation is the main indication; but it *should be entirely destroyed, or not touched*. On this account the incisions must be made in the healthy tissues, so as to ensure the complete removal of the disease. The knife is the best mode of removing it where incision

can be practised; but when this is inadmissible, caustics must be resorted to. Of these, arsenic is the best, as in the paste of Manec. The conjoined use of excision and caustic will in many cases be more successful than that of either separately. When the disease is too extensive for the reasonable hope of cure, palliative treatment can alone be adopted.

Cancroid of the lower lip shews itself sometimes as superficial hypertrophy of the epidermis, at others, and more frequently as an affection of the papillæ. The effects of local irritation are most conspicuous in the lower lip, where the injurious consequences of the contact of the pipe are seen, as well as those of the ineffectual use of caustics. In operating for cancer of the lip, the portion removed should be large, even, if necessary, to the removal of the entire lip, together with any engorged glands. If the ulceration is recent and superficial, the arsenical paste may be applied, taking care that none gains access to the mouth, so as to be swallowed.

Cancroid of the face is more commonly seen on the nose and eyelids than elsewhere. On the cheek it assumes the papillary form, as also on the eyelids; but here there is generally the addition of fibro-plastic elements.

The excavating ulcer (*ulcere rougeant*) is commonly seen on the nose; it commences as a tubercle, and then ulcerates to an indefinite extent. The progress of this is slow, and numerous facts sufficiently attest its curability. The mean duration appears to be about nine years.

Cancroid of the penis generally originates either on the surface of the glans, or internal surface of the prepuce. It is chiefly composed of hypertrophied papillæ, and is specially frequent in persons who are the subjects of congenital phimosis. The orifice of the urethra is concealed by the exuberant vegetations. The duration varies from a few months to ten years.

The "chimney-sweep cancer" of English writers is a form of epithelial cancer; but sometimes it contains true cancer elements. It commences as a wart, which is followed by ulceration. It is curable in its early stages.

Cancroid of the vulva is generally hypertrophic, commencing on the nymphæ, where it may extend to the whole vulva, as well as the anal region. Its progress is slow, and it chiefly affects young women. Its results are fatal, unless it be removed entirely in its early condition. Anti-scorfulous remedies are specially beneficial.

Cancroid of the limbs generally attacks the dorsum of the hand or the ankle. Cancroid sometimes appears on mucous membranes. We have seen it on the neck of the uterus, and on the tongue, sometimes in the hypertrophic form, at others as an excavating ulcer. Once we have seen it on the arachnoid.

Keloid offers some analogies to cancroid, especially in its tendency to relapse.

Spontaneous Development of Gas in the Blood as a Cause of Sudden Death.

In the *Presse Médicale de Bruxelles* is published a memoir on this subject, by M. Durand Fardel. The

case which forms the basis of the memoir, is that of a lady, aged 56, who, being at Vichy with her husband, proceeded, as is the fashion, to take the baths, though there was no necessity for them as regards her general state of health, which, on the contrary, was remarkably good. It appears that on July 20th, 1850, she took her second bath at four A.M. She had been over night in her usual state of health. In walking to the baths she noticed that her breathing was shorter than usual, and the attendant observing her condition advised her not to bathe that day. She, however, did so, and remained in her bath half an hour. When she got out she felt uncomfortable, and in a "few" minutes sunk exhausted into a chair. Respiration now became very difficult, and in a few moments she was dead.

M. Durand Fardel, who was on the spot immediately, found her still covered with her bathing sheet. The face was pallid; lips violet; no froth on the lips; limbs flaccid; and heart's action completely ceased.

The autopsy was made twenty-two hours after death, the 31st of July, at three o'clock in the morning. The body presented no appearance of putrefaction, there being some lividity only on the depending portion of the trunk and members. The heart was very large; the right cavities distended with liquid blood, rather violet coloured than black, syrupy, very frothy; the bubbles of gas enclosed were some (very numerous) as big as the head of a pin, others less common, as large as peas. When pressure was applied over the course of the two venæ cavæ, the blood which flowed into the right auricle was frothy, like soap and water; the parietes of the right cavities of the heart presented a superficial violet colour; the left side was completely void of blood, and not coloured; the left ventricle was considerably hypertrophied; the orifices of the heart did not present any appreciable alteration, as also the aorta. All the abdominal venous system was distended with violet and frothy blood; numerous bubbles of gas were also found in the blood of the splenic and portal vein. The lungs filled the chest, presenting a few adhesions, and some appearances of emphysema; their colour was reddish outside, but of a deeper tint internally, where they presented traces of considerable sanguineous congestion, without infiltration of blood. There was considerable frothy congestion in the more depending parts. The bronchi contained some whitish frothy mucus. The abdominal organs presented nothing more worthy of notice than a considerable sanguineous congestion of the liver, spleen, kidneys, and a remarkable congestion of the veins of the epiploon and mesentery. The epiploon was loaded with fat; the stomach rather large, and containing about half a glass of clear colorless mucus. The intestines were not opened. The encephalon did not present the same degree of congestion as the other organs; the sinuses of the dura mater contained only a little liquid blood, not frothy. The brain and origin of the spinal marrow, examined as soon as possible, appeared completely natural, a little injected with blood; no bubbles of gas appeared in its vessels.

The author publishes this case in all its details, as

science possesses as yet very few cases of this kind. The observations of Morgagni, wanting in details, do not allow of a positive judgment. M. Reyrolles, in two cases of death by hæmorrhage, found the blood frothy in the heart and veins.

Finally, M. Ollivier of Angers, published a case (*Ann. Gen. de Méd.*, 1838) which leaves no doubt as to the existence of the disease which M. Durand Fardel observed in this case. A curious circumstance, doubtless observed before, enabled M. Durand Fardel to state the existence of gas at the moment even of death. The bleeding performed at the arm gave issue for more than a quarter of an hour to blood, which, trickling from the vein of a body deprived of life, carried with it numerous bubbles of gas.

To what cause can the origin of this gas be attributed? This is a question still undetermined, and which may be perhaps solved at some future time by the chemical analysis of the gas found in the blood. Whatever it may be, the observations of M. Durand Fardel tend to prove that it is owing to a spontaneous exhalation from the veins, caused by spontaneous alteration in the crasis of the blood, of which we are ignorant.

[This case is still further important in its connection with those cases of sudden death after delivery in which air has been found in the blood, and is supposed to have entered by the uterine sinuses. May it not in these cases depend, as in M. Fardel's, on a spontaneous generation of gas?—ED. P. J.]

Correspondence.

ON PRIVATE LUNATIC ASYLUMS

To the Editors of the Provincial Medical and Surgical Journal.

SIRS,—In conversation with various intelligent members of Society, lay as well as professional, I find the above subject has attracted considerable attention, and is invested with an interest at the present time, which calls for a more extended discussion, and if your pages be still open to such a theme, I solicit another portion of your space in one of your earliest issues.

When my former letter, published in your journal of the 21st of January, was penned, I was not prepared to believe that the noble Chairman of the Commissioners in Lunacy could possibly have made use of such a statement as has been attributed to him by the public press. It is reported that Lord Ashley, at a late meeting in one of the midland counties, said that "he hoped to live to see the day when every private asylum in the kingdom would cease to exist." Now, Lord Ashley, I should suppose, notwithstanding his official relations, is at liberty to fully express his opinions on this subject, freedom of discussion being the birthright of every inhabitant of this realm, and constituting, indeed, one of its main glories; but I think you will agree with me, that it specially behoves an individual holding the conspicuous position he has hitherto done in public estimation, to be cautious as to the grounds on which he allows his actions to be determined in any public movement. I do not think any one does or can suspect

Lord Ashley of any but the most honourable motives in his philanthropic career, but his judgment is equally liable with that of all others to be impugned; and it is my opinion that the above bold and rather radical statement, like the recent dictum of a celebrated lawyer, "that no lunatic not dangerous to himself or others, should ever be confined in a lunatic asylum," would have been better unsaid. But we have not yet to learn that great men may, and do err, and we must leave his lordship to answer for himself. It is necessary to observe, however, that such an asseveration coming from such a quarter, and in such an age, is rather startling and significant, and ought to awaken from his slumbers every party who has an interest at stake in the existence and maintenance of a private asylum. Whether intended or not, we seem to have no alternative left, than to look upon it as the sounding of the tocsin, and we can no longer with safety lull ourselves in our fancied security, otherwise our strongholds may be taken by surprise, and we shall be left to mourn over our fate without sympathy and without redress. Coming events are apt to cast their shadows before them; and, depend upon it, the day is portentous, and it is high time to put on our armour for the fight, and if we can show that we have any measure of right and justice on our side, let us resolve to act in concert, and not fail, when called upon, "to die hard." If public feeling, goaded on by notions of mistaken philanthropy, shall determine the extinction of private asylums, it will be well to prepare in time to make out our case for compensation, (for our right to this, we presume, will be as clear as that of the West Indian planters ever was to their twenty millions,) but as I only fear that such feeling has not yet been wrought up to this pitch of warmth and fanaticism, that it may be still oscillating and perhaps halting between two opinions, it seems better, in the first instance, that we, the proprietors of of these asylums, should take some pains with the community in order to give them a proper insight into the nature of private institutions as well as into the "arcana," should there be any, of their general management. As matters at present stand, and as I have shewn in my former letter, the reformers have certainly had everything their own way, the people having been admitted to only one side of the picture, but notwithstanding all this one-sidedness, if the numerous charges against us cannot be rebutted—cannot be met by counter-statements which may annihilate or at least weaken their power; and, further, when we call to mind that our detractors are active and we are passive, I repeat, our extinction is nothing more than a legitimate consequence of our own supineness and lethargy, and our tacit acquiescence in it will be regarded in no better light than as an evidence of our guilt and self-convicted criminality.

Now, it is hardly to be expected that Lord Ashley, with his acknowledged character for caution, would venture upon so general a condemnation of private asylums solely on the strength of his own experience, and it is an inquiry of some interest to us—the proprietors, to learn how his Lordship has been led to this conclusion; for there is undoubtedly involved in it the negative inference that, in his estimation, the very principle of a private asylum is essentially defective, that

the system is incurably wrong, and admits of no remedy but thorough extinction. Certainly, on the part of his Lordship, this is very bold doctrine to broach, but the fairness of our inference is undeniable. The most extreme reformer in general politics could not exceed it; indeed the latter goes no further when he contends that the evils and power of an hereditary peerage are so great that they can never be counteracted by present contrivance, and that there can be no true liberty for the people without its total extinction;—when he contends that the union of Church and State is accompanied with such fearful consequences, that it is useless attempting their reform without first entirely breaking off their alliance, &c., &c., &c.; but as these views are not participated in by the mass of sober and reasonably-minded men, so in like manner I fancy the radical notions of his Lordship in respect to the irremediable nature of the evils of private asylums, will be liable to share the same fate with the community in general. Now, in the absence of positive information, we must briefly speculate as to the mode in which Lord Ashley has been led to these extreme conclusions. Of course he is very familiar with the news of the day, as well as the literature of the age, and no doubt, he may have had a small share, by virtue of his office, of even personal experience; but I should say that the representations, derived from these various sources, highly coloured though they have been, would hardly have emboldened him to come out so strongly, and we are driven to the unwilling alternative of suspecting (and we may be surely excused suspecting, as suspicion seems the order of the day in these things) that the Commissioners themselves have been reporting unfavourably of us *en masse* behind the scenes. However, this may be, the noble Chairman seems to have come to a decision on the question, and to say the least, probably more may be due to the Commissioners for having aided in the result than we would fain believe.

The question, however, must not rest where it is at present; there must be a more thorough understanding on this point; and Lord Ashley, on consideration, must feel himself called upon at once to speak out more distinctly the meaning and scope of his observation. This much, at least, is due to the proprietors of private asylums; for really such an announcement, if it have its legitimate effect, is calculated to paralyze all their energies, and seriously interfere with the further investment of capital in this department of science. I fear, also, it may come to have another and perhaps more serious effect; for it may be the means of throwing additional impediments in the way of the Commissioners exercising their usual supervision with efficiency and satisfaction, for Lord Ashley's experience of mankind must, or ought to have taught him, that laws may be rendered so exacting as to goad people on to rebellion; that the sense of right and wrong, and we may, perhaps, be excused saying, even honour, small though this latter may be in the breasts of proprietors of private asylums, may be wounded, suspicions and jealousies may be engendered, and the respectful feelings hitherto subsisting between the supervisors and the supervised may be greatly interfered with. I believe it is a general fact and rule, admitted from Grotius downwards to Blackstone, that to ensure ready, and willing, and

obedient compliance to the laws, the framers must take care that they accord, as far as possible, with that sense of common justice and fairness, naturally inherent in mankind. The law of lunacy, strange to say, in more senses than one, appears destined to be rendered perfect and infallible; seems singled out for special experiment. Because insanity refuseth to be bound in by strict definition;—because the shades of sanity and insanity are so fine that the most copious and expressive language faileth to mark out their respective boundaries;—because a “Nottidge Case,” will now and then occur on the scene;—because, forsooth, these rare and exceptional instances have happened on a subject confessedly the most difficult and abstruse in the whole range of medical or legal science, has the whole system of management, each time of their occurrence, to be stirred up afresh to its very foundation, and triumphantly paraded as an argument showing the irremediable abuses of private establishments. We admit that painful cases have come to light, and we profess to have humanity enough left to lament them; but we at the same time are equally sure that such cases will occur again, despite of the most refined statutory enactments, and we demur, “*de toto*,” to the conclusions which appear to have been drawn from them. I appeal again to your readers whether, with the view of preventing the recurrence of these things, it is wise—it is necessary to abolish private institutions for the insane. By parity of reasoning we should be called upon to abolish the office of judge and trial by jury, because many innocent men, as has been afterwards proved, have suffered imprisonment and even death at their hands; further, shall we abrogate the Poor-Law because many instances have come to light where parties have been hungered to death through the difficulties attending its satisfactory administration? Again, why is the office of union-surgeon not extinguished, when it can be shown that in some few instances men have died without being able to obtain his services owing to excessive engagements? The reason is pretty obvious to men of experience. In all human affairs it is a good thing to aim at perfection, but there is no reason in becoming desperate when we fail to attain it. Let abuses as they arise be reformed, but in accordance with the dictates of cool and sober experience. We repeat, it would be very uncandid to deny that certain cases have occurred which were calculated to arouse public attention, or that many useful reforms in the law of lunacy have resulted from the attention of the community having been so directed. To deny this would be tantamount to disbelieving in the possibility of human progress; but public feeling soon tends to right itself and come to a due equilibrium, when the facts of any case awaiting its decision are truly and faithfully represented, without colouring and without distortion; but who can say that such has obtained with regard to the subject of lunacy; indeed, who can deny that a great amount of pseudo-sentimentalism and mawkish sympathy has been unnecessarily expended upon it.

We next approach one of the most important parts in this discussion. Supposing Lord Ashley succeeds in his attempt to annihilate private asylums, it is very necessary to inquire what he proposes to substitute in

their place. Does he intend to remove private lunatics to the county establishments? or is he about to restore the cottage system, and store them up and down again amongst farm houses? or rather, does he not purpose to erect special institutions by means of charitable subscriptions, and in the event of these failing, by the aid of county-rates or the consolidated fund, something on the principle of the Northampton and Manchester Asylums; and when all this has been done, to go out into the highways and hedges, and compel them to come in. We must presume that his Lordship at least imagines he sees his way clearly on this point, and possibly he may be gifted with a more extended vision than ordinary mortals, but he must bear with us taking the liberty of cautioning him as to the very delicate ground on which he here treads, and of expressing our deepest conviction that he is about to undertake a task which will prove too great for him.

We believe it is a general rule, as we have attempted to show in a previous letter, that there is a constant tendency in mankind to be jealous of all establishments officered by salaried superintendents; and for one main reason, amongst many others, that it is generally difficult to fix upon a responsible head. The public prefer to deal with individuals rather than a Committee of Governors; and we must repeat our impression that should the Commissioners succeed in inducing the Legislature to refuse to license any longer private institutions, they indulge themselves in a delusion when they anticipate the day that persons of means, or those who have any option in the matter, will consent, as a general rule, to send their friends to public asylums. No doubt exceptional instances may now and then occur, where the Governors can meet with a Tuke, or a Conolly, or a Pinel, to act as directors, whose high moral and well-established characters would at once inspire sufficient confidence. But in a great undertaking of this kind, intended to be adapted for the whole community, it must be recollected that their main management, after all, will have to be entrusted to men of average attainments and average feelings;—in short, to common fallible humanity.

Having entered so far into the general argument, and having ventured to express our great misgivings as to the success of the institutions which it is proposed to substitute for those whose existence time-honoured custom has long tolerated, if not sanctioned, it seems necessary that we should now clearly and explicitly state some of the probable reasons which induce the public to prefer private asylums. In a former letter we slightly glanced at this subject; but we propose now to enlarge upon it. And, in the first place, we affirm that the public prefer them because there is generally one recognised responsible head, supreme in control, and amenable to no other authority, and who is influenced by motives of self-interest to be affable and approachable, prompt and business-like in his habits;—one who is dependent for his daily bread on his daily exertion;—one who is dependent for success on the candour and good faith which he observes towards his patients and their friends;—one who has time and opportunity to pay individual attention to individual cases.

In the second place, the public prefer private asylums because they are, comparatively speaking,

private;—because they are more limited in extent, and that, therefore, their friends can receive more special attention;—because they believe that a greater variety of diet is practicable in them;—because they feel that they can make it worth the while of the proprietor to grant a greater number of little nice indulgencies, which they conceive will contribute much to the invalid's comfort;—because they can more freely and oftener correspond respecting their friends;—because they feel more at liberty to visit (whether judiciously or not is another question) whenever their feelings prompt them to such a course. And, contrast all these privileges and advantages with those of an asylum containing from 300 to 500 inmates, and perhaps the public will shew themselves not very undiscerning in imagining that a private asylum will suit their tastes and views better, and prove more acceptable to their feelings.

That the above is no factitious representation—no coloured exaggeration to gain an object, we appeal to every medical man of experience in these matters; indeed, to any one who has studied mankind, and who knows something of the impulses and emotions which determine the springs of human actions. Not a year passes over our heads but we receive parties into our establishment who might have obtained admission into the county one (and if our fees were less, we feel that we should receive many more); but the friends prefer to try them for a few months with us previously to their adopting this, in their opinion, extreme course, and they make great exertions to maintain them; and the reasons assigned on their part are embodied in the statements above made.

We cannot well conclude this letter without briefly alluding to the proposals recently set forth by Dr. Henry Munro, although we feel that we might safely leave him in the hands of your correspondent E. B., who, if not so wordy, has at least shewn himself greatly his superior in experience and wisdom. We have really no wish to impugn the purity of motive, or suspect the disinterested nature, of the benevolent aspirations which seem to have actuated Dr. Munro in his present course; but he should recollect that in a movement of moment it is as necessary to use the head as the heart, otherwise we shall be apt to make very poor and profitless advisers. He might also have been induced to act more cautiously by recollecting that he is the scion of a family long distinguished in this department of knowledge, and that there devolves upon him the maintenance of the honour of a character so well and so richly earned. His reasons for increased supervision are, in our opinion, of the most flimsy and gratuitous description, and make us disingenuous enough to stamp them at once as the concoction of the cabinet, and not the offspring of calm and sober experience. Your space will certainly not permit of our entering into detail; but, like E. B., we beg to give an unqualified contradiction to each and every one of his four propositions; and we cannot restrain ourselves from saying that the appointment of any Assistant-Commissioner in Lunacy would be a piece of the most jobbish, meddlesome, and unnecessary legislation, in a small way, that was ever palmed upon an unsuspicious and industrious people; and we sincerely hope that not a sixpence of our hardly earned income-tax will ever be

misappropriated to such a purpose. We have supervision enough. If six or seven clandestine visits in the course of a year, by parties endowed with such tremendous powers as the present Commissioners, are not adequate to regulate and keep in respectable order lunatic asylums, and prevent the creeping in of excessive abuses, the sooner the extinguisher is applied the better. The public, we believe, if let alone, are sufficiently satisfied with the protection afforded to the liberty of the subject by the last Act of Parliament. We never recollect an instance in which any party to whom we have been called upon fully to explain the safeguards established by law to protect Her Majesty's subjects from improper confinement, has considered them inadequate; but we have a very distinct remembrance of a case (for it happened very recently) where an affectionate brother of high moral character, and of considerable mercantile notoriety, whilst performing the painful duty of consigning a near relative to our care, observed that he thought such extreme supervision must be unnecessary in private asylums, but perhaps called for in public institutions. On requesting him to state his reasons for this conclusion, which we informed him was opposed to that of many very humane men at the present day, he replied "that a regard for character and worldly success should do much towards ensuring proper and humane treatment of private patients."

We shall dismiss for the present this part of the subject by candidly observing that our experience inclines us to the belief that the inspection of lunatic asylums will always prove a rather difficult as well as delicate task, and will probably never be rendered so perfect as fully to meet the whims, and caprices, and fastidious tastes of certain gentlemen who sit at home in their easy chairs, and who are seldom seen on the field of battle; and this difficulty will attach whether the establishments be private or public; for we profess to know even something of the internal management of the latter, and therefore would warn our detractors in pointing them out to us as paragons of perfection. Much will always have to depend on the good sense and moral attributes of the medical superintendent; and the public have penetration enough to see this. But we have certainly our doubts as to the soundness of the principle of inspection which is pursued at the present day. We believe that inspection is necessary, and if properly executed cannot fail to do good. We believe that all reasonable suggestions of the Commissioners will be received in a proper spirit by proprietors of these houses;—that they will be thankful for any novel plans which may be submitted to them to assist them in the discharge of their onerous duties; but why allow themselves to be egged on to anything even approaching an undignified course by the current fashion of the day of making molehills into mountains?—why come down upon us predetermined to find fault?—why plant themselves in different departments of the house and cross-question our domestics, with the obvious intent of eliciting inconsistent reports?—why deny the superintendent credit for some few grains of conscience and integrity of purpose? We question either the fairness or philosophy of this system; and we are glad to say that we cannot yet go

this length in our belief in the depravity of human nature. The banker trusts his clerks with bags of gold;—the money-receiver at the entrance of a restaurant, entertaining hundreds, takes your word and statement; and experience seems to warrant a continuance of the plan. But, lo! the proprietor of a lunatic asylum must not be entrusted with even the honour and confidence awarded to the frequenter of a pot-house.

Before we conclude you will perhaps indulge us with one word in reference to Dr. H. Munro's scheme for establishing asylums for the middle classes; and we are sorry that we cannot consider him here any more happy than in his arguments for increased supervision. Dr. H. Munro must really suffer from a morbid overflowing of benevolence. The sum and substance of his appeal amounts to this,—that it would be a good thing to erect asylums for the middle classes, because their limited resources render it difficult for them to maintain their friends at private ones; and it wounds their feeling of pride to be accommodated at the expense of the county. Now, abstractedly considered, we dare scarcely deny the truth and reasonableness of these propositions; but we think we are safe in contending that it would be equally a good thing to subscribe a large fund to assist the middle classes to pay their ordinary doctors' bills, their lawyers' bills, and their Government taxes;—to assist the bereft widow in bringing up her fatherless children, and keeping them from the workhouse;—in short, a fund to assist every man, woman, and child in this kingdom who have the usual worldly difficulties to contend with. But we would ask, is there no danger that such a fund is calculated to strike at the root of our national greatness, and undermine its very essence, namely,—self-reliance and independence of feeling; for who, with such resources at command, would long impute these noble principles as virtues? Nay, would not the inevitable result of such a fund be reckless dissipation and hopeless improvidence. We are here reminded of a sentiment, to which at times we are half inclined to subscribe, the remark of a celebrated foreigner, who, on having had pointed out to him our numerous hospitals and benevolent institutions, as specimens of our national greatness and pride, replied, that he should rather look upon them as evidences of national disgrace, for they indicate one or other of three things,—either that the people are very idle, or very improvident and dissipated, or the rewards of labour are very unfairly and unequally distributed amongst them.

To say the least, our Saxon blood recoils at the very idea of pauperising the middle classes of England for this purpose, and rendering them recipients of charity. True benevolence, Dr. H. Munro may rest assured, will always find abundant scope for exercise. Too many objects, we fear, for its gratification are constantly falling out in complicated societies like ours, without devising means for their artificial creation; and it has really become a question with us whether indiscriminate almsgiving or unlimited selfishness be attended with greater evils to society. We feel that the best and soundest part of benevolence consists in readily adopting all those political expedients which tend to beget industry and exertion amongst the people, and to

ensure a proper and equable distribution amongst them of the fruits of their labour; and that excessive almsgiving is only a very secondary ingredient in the philosophy of social improvement.

To conclude, our task has been a very ungracious one of having to set ourselves in seeming opposition to principles and practices which, when properly carried out under the guidance of reason and judgment, reflect infinite credit on our very race, and constitute, indeed, some of the great redeeming traits in our fallen nature. But the sense of duty not unfrequently works in antagonism to the feelings of the heart; and we have only enunciated what we believe to be based on equity and truth.

I remain, yours, very obediently,

AN ADMIRER OF TRUTH.

ON UTERINE HÆMORRHAGE.

To the Editors of the Provincial Medical and Surgical Journal.

GENTLEMEN,—I was much interested in the perusal of the paper on "Uterine Hæmorrhage" by Mr. King, contained in your journal of the 31st ultimo, but was somewhat surprised he made no mention, amongst other means for the treatment of internal uterine hæmorrhage, of the injection of cold water into the cavity of the uterus, for the purpose of inducing permanent contraction of that organ, after the expulsion of the placenta. In three cases of internal hæmorrhage I have applied cold water in this way, with the most complete success, and unattended with any unfavourable symptoms afterwards. In one of them napkins, saturated with cold water, placed on the abdomen and pubes, and pressure with the hand over the fundus uteri, had been applied for some time, but with the effect only of retarding, not stopping, the gradual increase of the organ. Having sent for a syringe, I injected a quantity of cold water into the cavity, and immediately perfect contraction ensued. It is immaterial whether a common enema syringe or an elastic bottle be used for the purpose, provided the tube be sufficiently long to be carried completely within the os uteri; by this method the uterus is thoroughly emptied of its contents, not leaving, as is frequently done after the application of cold externally, a large coagulum within, which, undergoing decomposition, causes offensive lochia, and not infrequently uterine phlebitis; and it is also less likely to be followed by serious consequences than the introduction of the hand within the uterus, as recommended by some authors, although Mr. King says "the only contracting power in this case (internal hæmorrhage after delivery) is cold water."

With regard to the action of the *secale cornutum*, I think it has certainly the power of originating uterine action, not merely of stimulating it, but the dose requires to be frequently repeated, and is undoubtedly more efficacious when combined with bichloride of soda recommended by Dr. Rigby.

I am, gentlemen,

Yours very truly,

F. P. C.

April 3, 1852.

THE NEW MEDICAL REFORM BILL AND THE TITLE OF DOCTOR.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I perceive that the New Medical Reform Bill is particularly fastidious with respect to the use of the title of *Doctor*. No one shall use it, says the Bill, who has not an undoubted right to it.

Now, Sir, if the *Squires* of the country were as fastidious and particular as regards their title—*Esquire*, which is a territorial title, and as much a title of honour as *Baron*, *Count*, or *Duke*. How would your correspondents, who use that title, without any real right to it, feel?

Every blue-bottle doctor, now-a-days, sets up for being an *Esquire*, many of them not knowing that they are using a title of honour; yet the real *Squires* say nothing in the way of objection, but on the contrary, often courteously address their medical attendants, however humble their grade may be, by that title.

The barrister and the M.D., are by law *Esquires*, as the attorney is a *Gentleman*; and as such they rank in society; but the apothecary or the surgeon is not an *Esquire* in right of his profession, and their using that title is as great an usurpation and intrusion as using the title of *Doctor*.

Now, Sir, I would suggest to you, not to be so exclusive about the use of the title—*Doctor*. It is a convenient title for the medical attendant, and I see no reason why physicians should have a monopoly of it.

The people always will say "*our doctor*," whether *their Doctor* be physician, surgeon or apothecary, and I think the medical attendant should have the privilege of styling himself by the title the people ordinarily give him, whatever his grade may be. But then, again, as you are going to have only one scale of education for all medical men, this distinction about title is the less tenable in your scheme. Some may, having passed the examination, join the College of Physicians, and some the College of Surgeons, whilst others will remain general practitioners; but if they are to be educated alike this invidious distinction of title would be unjust. Let them all be *doctors*, for *doctor* is the title the public will give them; and to keep it from being a *nickname*, let it be their rightful title.

But it is intended that those who may select to join the Colleges of Physicians and Surgeons respectively, shall have to undergo another examination; if so, your Medical Reform will make little or no change beyond a superseding of the Apothecaries' Hall in its functions of examining and giving a licence to practise. All those under the new law who shall not have joined the Colleges, will be looked upon as mere apothecaries under some other title—a title it appears not yet settled on, but that title as the act, or rather proposed act implies, must not be *doctor*. Nor can it be surgeon, for the using of that title would be a usurpation, without the diploma of the College.

When I was young there was a medical practitioner who kept a shop in a certain city, and he had on the door his name, with surgeon-apothecary and midwife after it. It so happened that he was a good-looking

fellow, and that a wealthy heiress fell in love with him, and married him. He took *her* name, and having moved into a neighbouring square, put it on his door after his own name, but no surgeon-apothecary or manwife. His own name was Davis, the wife's maiden name, which he adopted, was Issadore, rather an uncommon name no doubt, and many of his patients seeing that the former titles were no longer on his door, came to the conclusion that Issadore was a new technical word, meaning surgeon, apothecary, and midwife altogether.

It is, I submit, Sir, just such a word we want as a title for the new-fangled practitioners, if the use of the title of *Doctor* is to be prohibited. But I am for the good old title of *Doctor*; it means all, and it is short and handy, and every one has it by heart, and will apply it to the medical attendant in spite of all the penal laws you can enact.

Your constant reader,
M.D., EDIN.

London, April 3, 1852.

MEDICAL BENEVOLENT FUNDS AND COLLEGE.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—By the exertions of Messrs. Newnham, Daniell, and Propert, the subject of Medical Benevolent and Provident Funds or Societies has at length been forced upon the attention of the profession, and a decided conviction of their necessity and utility established. This result, upon which I sincerely congratulate those gentlemen, would, I believe, have been much sooner realised had they not ignored the existence of numerous societies which have been long established, and have accomplished a large amount of benefit in their different spheres. My object at the present time is not to discuss the peculiar claims of the purely Benevolent Fund which is advocated with untiring zeal by Mr. Newnham, or the society of a mixed character so ably supported by Mr. Daniell, but, having satisfied myself as to the merits of the Medical Benevolent College proposed by Mr. Propert, to submit for the consideration of the Council of that College, and the different County Medical Benevolent Societies, a plan which, in my humble opinion, will, at the same time that it promotes and expedites the establishment of the College, increase the usefulness of the local societies without interfering with their individuality or independence.

It is proposed that the College shall afford accommodation for 100 pensioners,—who shall possess an income of £15 a year each,—and a school for 100 boys.

The estimated outlay for site and the requisite buildings is £20,000.

The annual expenditure is estimated at £1500.

This gives an outlay of £200 capital for each pensioner and scholar, and an annual cost of £15 for each scholar.

No mode of electing or appointing the pensioners and scholars has as yet been proposed. The combination of election and nomination appears to me to be desirable and practicable. A certain number of appointments should be filled up by the votes of the subscribers of less than £200, and every individual or society subscribing £200 and upwards should have the right to nominate one pensioner and one scholar for every £200 subscribed, subject to the conditions that every pensioner so nominated should be possessed of, or have guaranteed for him, the sum of £15 a year, and that

for every scholar so nominated the sum of £15 shall be paid yearly.

The President, Vice-Presidents, and Treasurer of every society subscribing to be *ex officio* members of the Council.

I respectfully submit this scheme to the consideration of the Council of the Medical College, believing it will harmonize with the steps already taken, and tend to facilitate and hasten the accomplishment of their benevolent object.

There are several County Benevolent Societies existing, which have accomplished, and continue to confer, a large amount of benefit in their several localities. I will take the Kent, with which I am connected, as a specimen of them. The remarks which apply to this will most probably apply to the others.

The Kent Medical Benevolent Society was established in the year 1787. The amount of capital accumulated in the year 1851 was £6450 in three per cent. consols, (which sum is on no account to be diminished below £3300 stock,) producing an annual income of £186. 8s. 1d. The number of members at the same period was 141, who subscribe £1. 1s. each annually, making £148. 1s., thus giving an annual income of £334. 9s. 1d.

The number of members deceased is 162, of whom forty, or nearly twenty-five per cent., have received assistance to the amount of £10,827. 15s. since the establishment of the society. The number of recipients have, on the average of the last ten years, been 8.5, who have received annual grants to the amount of £225. The grants made in 1851 were, £35 each to four widows, £30 each to two widows, and £10 towards the education of the son of a deceased member, making a total of £210.

I think the time has arrived when the Society ought to take into their serious consideration, the policy of increasing their capital without any scheme for its ultimate appropriation. Should the Council of the College adopt the plan proposed, I should recommend that the sum of £1000 should be subscribed to that institution. This would reduce the annual income by something less than £32, but would afford the means of granting a house and home to five individuals, and securing a good education and board to five young persons, at a cost of £15 each, or £50 less than it could otherwise be obtained for. Should the ten nominations be filled up, and the Society pay the whole of the pensions—viz. £150 a year—there will still be an income of £150 to appropriate to those cases which it would be desirable and necessary to assist as heretofore, and which, judging from the past, would be amply sufficient for the purpose. It, however, by no means follows, that the Society should in every case pay the pension for their scholars; a nomination would in many instances be a great assistance. The necessary regulations for the appropriation of these nominations would of course be framed by the Society.

The adoption of this proposition would, I feel convinced, increase and extend the means of usefulness, without in the least involving the independent action of the Society, which is essential to its permanent existence and support. I am not acquainted with the actual number of societies existing, but I may mention the London, the Norfolk and Norwich, the Hertford and Essex, the Surrey, the Kent, and one in Yorkshire, I believe. A subscription of £1000 each from these would produce one-fourth of the required capital!

If by these observations the parties interested should be induced to adopt the propositions severally made, and thus hasten the consummation of a great and good work, I shall be gratified thereby, and am, Sir,

Your obedient Servant,

Dover, March, 1852.

GEO. SOULBY.

Medical Intelligence.

APPOINTMENTS.

Mr. Joseph Maclise, F.R.C.S., has just been elected Assistant-surgeon to the University College Hospital, in the vacancy occasioned by the resignation of Mr. William Cadge.

ROYAL COLLEGE OF PHYSICIANS.

The following gentlemen were admitted Members of the College on Monday, April 5th:—Dr. Henry Folkard, Old Brompton; Dr. Liebermann, Clapham Road; Dr. Prout, Royal Hospital, Chelsea; Dr. Salter, Montague Street, Russell Square. Also Dr. Osborn, Southampton, was admitted an Extra-Licentiate.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 26th ultimo:—Richard Sumner Fowler, Bath; Henry Homer Grainger, Skipton-in-Craven, Yorks; William Harboard, Hull; Frederick Ashton Heath, Manchester; William James, Newport, Monmouthshire; John Lister Bertram King, Belgrave Square; Samuel Buckland Mitchell, Kingston-upon-Thames; Constantine Casidi Readé, Army.

The following gentlemen were also admitted on the 2nd instant.—John Mathew Burke, London; George William Carr, Kincardine, Upper Canada; Charles Richard Crossley, Ashby-de-la-Zouch, Leicestershire; John Brendon Curgenvin, Highgate; William Evans, Anglesey; William Richard Grylls, Sydney, New South Wales; William Haynes, Hon. East India Company's Service, Bengal; Iberson Izod, Birmingham; William Young Geeves, Sharrow Grange, Yorkshire; Charles Lee, Woodbridge, Suffolk; Robert Francis Symmons, Bures, Suffolk.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on the 25th ultimo:—Thomas George David Davies, St. Andrew's Court, Holborn Hill; Samuel Drew, Cornwall; Alfred Freer, Stourbridge, Worcestershire; John Hemming, Kimbolton; Alfred Jackson; John Moysey Bartlett Langworthy, Modbury, Devon; Patrick James Mullarky, Margate; John Vinall, Sutton Place, Hackney; John Wilcox, Birmingham.

The following gentlemen were also admitted on April 1st:—William Field Bellin, Great-Yarmouth; George Vause Birks, Manchester; Thomas Quiller Couch, Polpero, Cornwall; Charles Richard Crossley, Ashby-de-la-Zouch; Alfred Hedger, South Street, West Square; Arthur Robert Lomax, Hereford; Henry John Davis Mathews, Denmark Hill; Joseph Dunn Nelson, Exeter; Thomas White, Chester.

ERRATUM.—In Mr. King's paper "On Uterine Hæmorrhage," in our last *Journal*, page 168, second column, 20 lines from the bottom, for "on dividing the head" read "on dividing the cord."

TO CORRESPONDENTS.

Communications have been received from Mr. Perceval, Justitia, Mr. West, Dr. Russell, and Dr. Nelson. *Stockport Medical Society*.—The resolutions passed at the monthly meeting of the Stockport Medical Society, upon the Medical Reform Bill, will be inserted in our next.

MEDICAL BENEVOLENT COLLEGE.

PRESIDENT.

THE EARL MANVERS.

TRUSTEES.

DR. J. A. WILSON.

DR. R. LEE, F.R.S.

W. FERGUSSON, Esq., F.R.S.

JOHN BACOT, Esq.

BENJAMIN PHILLIPS, Esq., F.R.S.

TREASURER.

JOHN PROPERT, Esq., 6, New Cavendish Street.

IT affords the Council much satisfaction to publish the **THIRD LIST OF CONTRIBUTORS** to the COLLEGE, and to acknowledge the cordial and efficient co-operation which has been afforded by those gentlemen, who, in acting as Honorary Local Secretaries, have so nobly assisted the Council in the success that has hitherto attended their labours; and as the Council confidently hope, with the continuance of this support, to be in a position in June next to lay the first stone of the College, they trust that other gentlemen will volunteer their services, and assist them to accomplish that desirable object.

The Council have the gratification to state that, through the munificence of a member of the Profession, a piece of land consisting of about eighteen acres, which will afford an eligible site for the College, is on the eve of being transferred to the Trustees, on the most advantageous terms.

The Laws for the Government of the College will be ready for circulation in a few days, a copy of which will be forwarded to each of the Honorary Local Secretaries.

HONORARY LOCAL SECRETARIES.

Several returns from Honorary Local Secretaries having arrived too late for insertion in the present List, the FOURTH will be published at an early period.

Gentlemen desirous of acting as Honorary Local Secretaries will oblige by communicating with the Secretary.

Further information may be obtained by addressing the Honorary Secretary, Henry Tudor Davies, Esq., 4, Hanover Square, where Subscriptions will be received, as well as by the Treasurer and the following Bankers:—Goslings and Sharpe, 19, Fleet Street; Coutts and Co., 59, Strand; Drummonds, Charing Cross; Glyn and Co., 67, Lombard Street; Scott and Co., 1, Cavendish Square; Messrs. Herries, St. James's Street; Messrs. Hoare, Fleet Street; the Union Bank of London, Regent Street, Branch; Messrs. Williams, Deacon, Labouchere, and Co., Birchin Lane; and by Cunliffe and Co., Manchester.

Copy of the Laws of the College may be had on application at the Office, and enclosing two postage-stamps.

By order of the Council,

Office, 4, Hanover Square, March 30, 1852.

HENRY TUDOR DAVIES, Honorary Secretary.

CLINICAL LECTURES
ON THE
PRACTICE OF PHYSIC,

DELIVERED IN THE
THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D., EDIN.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c.

LECTURE XIV.

ON THE MORBID CONDITIONS OF THE URINARY
ORGANS.

GENTLEMEN,—While dwelling, in the last lecture, upon the affections of the bowels, we had to consider one channel of excrementitious discharge, though certainly even the lower guts are not altogether mere conduit pipes of bodily waste, but are also the seat of sundry acts of secretion and absorption which seem requisite for perfecting the process of digestion. They are only, therefore, partly excrementitious, and their purifying functions are limited to those cruder and more insoluble forms of carbon and the earths which are not capable of being eliminated through the lungs, the skin, or the kidneys.

These latter organs, of which I am now about to speak in connection with their more mechanical appendages, are purely and entirely an apparatus of excretion, and nothing passes through them naturally excepting the results of bodily decay, or such matters as are entirely useless to the animal economy. Thus, you are aware, that almost all the organic compounds which enter the body are resolvable, ultimately, into carbonic acid and ammonia, along with an admixture of earthy and alkaline salts. The cruder refuse of the food (that which is never assimilated at all) passes, as just observed, by the intestines. Those elements which go to constitute the chyle, after being mixed with the venous blood—and more thoroughly so within the heart—enter the lungs to be formed into blood fit for reparative purposes. At this stage of the process, however, a considerable portion of the oleaginous or other carbonized particles are decomposed, with a view to the maintenance of the animal heat; and one of the results of this smothered combustion is a formation of carbonic acid gas, which is evolved from the lungs. In this manner, about eight ounces of carbon are eliminated by a moderate-sized man in twenty-four hours. A woman, while menstruating, discharges much less, but comes up to the male standard both before and after her period of uterine activity. Now, after the blood has left the lungs in an arterialized state, we are to bear in mind that almost all its waste, as well as that of the more solid tissues (excepting such as is evolved in the invisible perspiration), has next to be carried off by the kidneys. In the perspiration we only find a few alkaline salts and some oil; and as the bile secreted by the liver is not an effete matter, but is destined to subserve various important purposes in the economy, it is, as you

see, to the kidneys alone that we must chiefly look for the purification of the vitiated venous blood, in so far as regards the elements above-mentioned; and not only so, but all other soluble matters which may pass unchanged into the blood do here also find vent. Thus, on the assumption of soda, potass, iodine, or any such matter, it will soon be found in the urine. The colouring matter of the bile will also escape by this channel, and, in morbid states of the blood or kidneys, sugar and albumen.

Let us now briefly consider the physiological nature and constitution of these wonderful organs and their appendages, upon which the safety of the frame so completely depends. Tracing the apparatus from the orifice of the urethra, we first find a passage, lined with mucous membrane, and encircled by muscular bands of minute dimensions, the whole being enclosed by the usual areolar tissue. This passage, at its junction with the neck of the bladder, presents to us a very powerful sphincter muscle, naturally capable of preventing the escape of the urine, except under the motion of the will. So far it is a voluntary, or may be called a semi-voluntary, muscle; for while, to a certain extent, it is subject to the will, there is a point of resistance at which even the will is incapable of controlling it. The same observation applies to the muscular bands of the bladder itself, which is to be viewed merely as a convenient reservoir in the animal economy to preserve us from the constant distillation that would otherwise be going on externally. The bladder is also lined with a continuation of the above mucous membrane, underneath which we find a beautiful work of encircling and interlacing pale muscular fibres, invested, as usual, with areolar tissue, which is again covered with a serous coat (the peritoneum), except where it is attached in front, behind, and inferiorly, to other organs in its neighbourhood. Towards the upper and back part of this bladder we find the openings of the ureters, which narrow passages may next be traced up to the kidneys being of similar structure to the urethra and other mucous ducts. At their termination, we discover the kidneys lying upon the lumbar muscles, and embedded within those masses of suet which are commonly found in this situation. They lie outside of the folds of the peritoneum, with which they have no connection, and may, therefore, he said to be not in the cavity of the abdomen, but in a peculiar cavity of their own—the renal cavity, let us say. The shape and size of these organs need not be described to you,—they are too familiar to every one present; and I shall confine myself still to tracing the excreting passages upwards until we come to the ultimate vesicles and tubules which are the seat of elimination. We find, then, that the ureter proceeds from that small reservoir at the inner side of the kidney, called, in its different turnings, the pelvis, the infundibula, and the calyces; and that, into this irregular reservoir dip certain conical mammillæ,* these being simply bundles of tubules, which, distilling their contents through the points of the mammillæ, are traced inwards to the body of the kidney and into the cortical, vesicular, or secreting structure. In this course they

are found to branch dichotomously, and to diverge from one another like the hairs of a painting brush, so as to spread themselves over as much secreting surface as possible, until, at their widest stretch, they form the bases of the cones, where they either pass more deeply into the vesicular structure, in right lines, or wander hither and thither in a tortuous manner through the vesicles, each one ultimately terminating in one of those aqueous excrements called Malpighian bodies. The intimate structure of these tubes consists of a transparent basement membrane, which alone intervenes between the capillary expansion of vessels, on the one side, and the epithelial lining on the other. It is through those epithelial cells, when within the cortical portion, that the saline excretions are inferred, by observations, to be eliminated from the sanguineous current below, while the water that dissolves them is conceived to distil from the Malpighian bodies. Now, these Malpighian bodies are individually inclosed within the final rounded expansions of each tube, which, therefore, forms what are called their capsules. The bodies consist, essentially, of a wonderfully minute subdivision of vessels, being tufts of capillaries, formed conjointly from the afferent and efferent vessels. Each afferent vessel is a minute branch of the renal artery, which, after entering and ramifying in a tortuous manner through the capsule, is formed again, by rejunction, into one efferent vessel, which proceeds to pour its contents into that secondary plexus, or minute ramification of capillary vessels, which is found upon or within the expansions of the basement membrane of the tubes. The coils of capillaries within these Malpighian bodies are naked ultimate vessels, not attached to each other by any other structure, but distilling their watery contents without any intervening membrane, even of the thinnest kind. It is in these bodies, and from these vessels, that, as I have said, the aqueous portion of the urine is eliminated, while the saline excretions are considered to be separated from the blood of the secondary circulation in the intertubular plexus, through the agency of the glandular epithelial cells. Upon cutting a kidney through the centre longitudinally, you can see at once, by a coarse view, how beautifully the merely conducting or tubular portion is distinguished from the vesicular, cortical, or secreting part. You will also observe that it is covered with a thin but firm fibro-serous lining, which, in the healthy state, can be easily peeled off, showing the smooth, shining, and dark-brown surface of the kidney proper underneath. It may also be added, that within the parenchyma of the organ, as in all other soft organs, we find a similar fibro-serous tissue, which dips down into and surrounds, involves, and supports, after the manner of a skeleton, all the more yielding and delicate portions of structure. I shall only further recapitulate that the secretory circulation within the kidney seems to be in this routine. The arterial blood enters by the artery, which next subdivides, and sends a minute branch, called the afferent vessel, to each Malpighian body. Expanding there into a tuft of capillaries, it appears to part with a portion of the watery element of

the blood, after which these same capillaries reunite into another vessel (the efferent), which proceeds to empty itself into another capillary plexus, which surrounds the tortuous tubes, and is spread over their basement or primary membrane. Here the elimination of the true urinary elements seems to take place, after which the blood is conveyed back to its general current through the veins. The kidney exhibits to us one of the purest forms of mere organic or vegetative life, and has, consequently, very little connection with the sensorial nervous system. Its nerves are derived from the semilunar ganglion, which is formed of the great sympathetic, with a few connecting links from the pneumo-gastric. Thus much was it necessary to say as to the anatomy and physiology of the urinary system before descending upon its morbid conditions.

I shall now speak of some of its chief diseases in relation to functional or nervous derangement—anæmia, hyperæmia, and degenerations.

PARALYSIS, or the absence or defect of power, is not common in the kidneys in a simple unmixed form. Its more partial manifestation, as a mere torpor, is certainly very frequently seen, but that is, most commonly, due to a state of congestion, and is, therefore, not a primary or central affection. That which arises from narcotic poisons, such as opium, or from the depressing effects of certain morbid conditions of the blood, affords us a better instance of true paralysis, whether complete or partial. In the terrible pestilence of cholera asphyxia, or true malignant cholera, this paralysis of the kidneys seems to be the leading feature when the disease is profoundly observed. Here an intense poison is conveyed, whether directly to the nervous system, or indirectly through the blood, it is hard to say, but it is conveyed so as to depress the ganglionic organic centres in a most extraordinary manner, while the cerebral masses are little affected, except from secondary causes. It thus happens, though the intellect be clear, that the lungs, heart, and other involuntary organs, at once flag in their efforts, while the blood becomes cold and congealed; but above all, while a mere passive exudation of serum takes place through the bowels, and while the functions of the liver are arrested, the kidneys are also observed not to secrete at all. It is the utter suppression of function in these organs, leading to retention of the urinary elements, which ultimately leads to stupor, and to the fatal result. You may, by your treatment, maintain the respiration and circulation; you may stop the purging, restore the bodily heat, and liquify the blood, and yet you will fail in exciting the kidneys to action, and consequently lose your patient; in brief, if you can excite them to do their duty, the sufferer will probably live, but if you cannot—and it is not often that you can—he will most certainly die.

The disease has been named cholera asphyxia, from its more serious results being first noticed on such organs of perpetual and obvious action as the lungs. The kidneys are less open to common observation, and their condition, therefore, is less noted by the ordinary eye; but, from its effects upon them, as recognised by

the professional investigator, it might as appropriately be named *cholera morbus amurialis*.

The bladder, from its more immediate nervous connections with the spinal cord, is more apt to suffer from paralysis. This may proceed from any accident or affection of that great trunk, above the points whence the nerves are derived, and may involve both the common circular muscles and the sphincter. Such cases are familiar to you as evidenced in the constant dribbling of the urine from the orifice of the urethra, so soon as it distils from the ureters. You have observed this symptom in several of our spinal cases, leading to paraplegia; but, most remarkably, in the poor woman Shipp, lying in the top bed of the second ward, though even in her it has yielded, in a great measure, to treatment. In the more common instances of mere debility of the sphincter, in which the sensitive surface becomes so irritable that very slight quantities of urine excite the other muscles to a reflex action, overpowering the feeble resistance of the sphincter, and giving rise to frequent, and next to involuntary micturition, the treatment is commonly very successful. We have had numerous such cases amongst our out-patients, but they have all soon recovered. One little girl, aged 10, lately appeared before us, suffering especially from this inconvenience. She had been troubled for nearly two years, the water often coming away every ten minutes; yet, by the use of local cold bathing, with a course of iron and lytta, bland demulcents, and a belladonna plaster over the sacrum, she was soon able to retain her urine like other people. Mrs. Shipp was in a different plight. She had no power over the lower extremities, which, however, were very painful, and often drawn up by violent involuntary jerks, a curious feature in some of these cases. The urine dribbled constantly from her, and was one of her chief sources of annoyance. At the side of the second or third dorsal vertebra a large boil was observed, extremely tender to the touch, and the adjacent vertebræ were noticed to be displaced, apparently from osseous disease. This was a desperate case, (since removed to the workhouse infirmary,) but still a similar course of iron and lytta, as above, removed in a great measure this most offensive symptom, so that she came to retain her urine for two or even four hours at a time.

Of any SPASM in the kidney I know nothing at all, but it is by no means uncommon in the bladder and its sphincter, and commonly proceeds from some local cause of irritation, such as a stone, an ulcer, an enlarged and indurated prostate gland, rectum, or uterus, &c., or the presence of acrid urine, or an acrid diuretic or astringent, such as lytta or port wine. Thus, when spasmodic excitation of the muscular bands exists, there is frequent, distressing, and unavoidable micturition, or painful contraction, without any micturition at all, as then the resistance of the sphincter is reduced, and we have a strangury of the bladder, corresponding to a tenesmus of the bowels. But when the spasm is persistent in the sphincter, the muscles proper of the bladder or of the abdomen will be exerted in vain. The first case is to be subdued or modified by sedatives and

tonics alone, as functional appliances, but keeping our eye at the same time on any physical cause that may be present. The second is to be also met by sedatives, antispasmodics, and heat. Hence a dose of calomel and laudanum, with the warm-bath, will frequently induce micturition without any use of the catheter; though, when physical obstacles exist, they must often come under the surgeon, especially as regards urethral stricture, a prostatic enlargement, in which cases the smallest catheter will sometimes be refused admittance, so that, in this extremity, puncturation has to be practised, either in front or by the rectum.

HYPERÆMIA is to be next considered, as anæmia of such organs is rather a disease of the blood in general, unless it be only a diminished local circulation, depending on organic changes, in which case it rather comes under the head of degenerations.

The ACUTE HYPERÆMIA of arterial origin, is well known in the kidney under the name of NEPHRITIS, and is commonly caused by the presence of a calculus, or powerful and prolonged impressions of cold. It is not very common here, nor have we had any severe case. When it does appear, we have more or less severe pain and heat over the affected part, the pain extending by sympathy down the ureters into the bladder or root of the penis or testicles. The pain feels deeply seated, and is increased under the slightest bodily motion or stretch of the parts, so that the various muscles naturally accommodate themselves to the condition of the sufferer. Great febrile excitement exists, along with anxiety, and the stomach, especially, is apt to suffer from sickness and vomiting. This word—*anxiety*, so often employed by the physician, is one of which you ought to know the precise technical meaning. It does not imply what is commonly known as mental anxiety; but that indescribable instinctive, or inward organic uneasiness which seems to depress us so deeply whenever any necessary part of organic life is much disturbed, even though the mental consciousness be in abeyance. It is to be recognised upon the countenance, and other expressive parts, apart from all apparent sensation or understanding; and it is thus that you will often hear a patient in typhus, who, on being momentarily roused, will say he is quite at ease and all comfortable; but who will tell a very different tale by the *organic anxiety* which is printed upon his brow, lips, nostrils, and labouring chest. It affords a simple illustration of the double life of Bichat, a doctrine now so well established. Besides this localised pain, and the constitutional symptoms, you would also have to seek for other evidence in such a case, as derived from the nature of the discharges. These, in the first instance, from the actively-turgid state of the vessels would, in all likelihood, be sanguineous. Such presence of blood globules in a severe attack, would be sufficiently indicated by the bright red colour of the urine; but if any doubt existed, the microscope would at once clear it up. If not arrested at this stage, there would next be a discharge of pus, and this would also be easily tested by the microscope, if not sufficiently evident to the naked senses. If the inflammation ran very high, or

was long protracted, there might likewise be deposits of fibrinous lymph within the body of the organ, which, if not absorbed within a limited time, might displace the glandular structure, and produce a carnification of the kidney, quite similar to that of the lung. This, again, under degenerate action, or rather loss of action, might break up into sanious or granular tuberculous matter, of which we had a very curious specimen lately in the case of the phthisical patient, Margaret Williams, of the circumstances of which I shall remind you. She was admitted on October 22, 1850, labouring under laryngeal and pulmonary phthisis, accompanied with rheumatism. Of this latter complaint she had recently been relieved at the General Hospital, but she was extremely emaciated, and in deep hectic fever; though what I wish to draw your attention to is the fact that she also complained of a settled pain about the brim of the pelvis, at the left side, which she had experienced, more or less, ever since she remembered anything. Now this poor woman, aged 42, after being in the hospital one month, died, when, besides the universal diffusion of tubercle in the lungs, which were also reduced to a softened grumous state by inflammation, the right kidney was found preternaturally large—nearly double the natural size—while the left presented, externally, a white semi-transparent lobulated appearance like blisterstone, or more near the point, like blisters themselves on the skin. On opening it, there spouted out, with considerable force, a quantity of thin, sero-purulent matter, intermixed with tubercular lumps, like cream cheese. This matter was observed to occupy large sacculated recesses on the internal surface of the organ, or rather pouch,—for organ there was none—to the number of six or eight. In fact, the whole of the proper tissue of this kidney had been destroyed, and not a vestige of glandular structure remained. When the fluid was thoroughly evacuated, and the inside was washed out, it had exactly the honeycomb appearance of an old potatoe that has been hollowed out by minute insects into rounded chambers. The observations which I have entered upon this point in the large case book are as follow:—"The most interesting feature in this dead body, was the condition of the left kidney, which accounted for the dull pain which she had always had about the brim of the pelvis at that side. The primitive disease of the kidney, of whatever kind it may have been, (for she could give no account of it), must have been of old date, looking to its then state, and to the preternatural size of the other kidney, which had, doubtless, gradually conformed itself to the double duty thrown upon it, and thus become augmented in bulk. It is not likely that the primary disease had been an acute inflammation, as, unless it occurred in very early life, it would not have escaped her notice. Most probably it was a chronic inflammatory action, followed by degeneration, which had destroyed the proper structures of the gland and deposited in their stead at first, perhaps, a sub-organizable lymph, and then a sero-purulent fluid interspersed with granular matter, which at the date of the death had here and there become aggregated in masses resembling particles of

yellowish curd. Such may be inferred as the likely course of chronic inflammation in a debilitated subject, while in a plethoric constitution acute nephritis would more probably lead to an abscess, which might burst either outside or inside."

This renal inflammatory action may be propagated along the ureters, in which case the pain along the lines of these passages will be very marked; but this more commonly occurs in a chronic form, from some persistent source of irritation, such as a calculus seated within the pelvis of the kidney, or the continued passage of gravelly matter.

Cystitis, in the acute idiopathic form, is not a common disease, and most frequently occurs from some traumatic cause, such as external violent injury, the presence of rough and pointed calculi, acrid injections, or from such accident as the swallowing of cantharides. I have only known of one instance of acute fatal cystitis in this hospital, which was not traceable to any such causes as the above, but the patient was not mine, and therefore I am not at liberty to use the case in illustration. When it arises we have acute localised pain, greatly increased by pressure, ardent local heat, and some swelling over the pubes. From the irritability there is frequent micturition of small quantities of urine, in the same manner as there is rejection of food in gastritis, or of mucus in dysentery. Likewise we may have constant attempts to pass something, which never comes at all. By sympathy with the stomach, vomiting also generally occurs, and there arises a symptomatic fever, more or less violent according to circumstances. The discharges, under these symptoms, may consist of tenacious mucus, or blood, or pus, but the pus, of course, will only appear when the disease has advanced to its latter stage; and the same observation applies to the appearance of gangrene, if that should ultimately supervene. In that event the pain, from being extreme, will almost suddenly cease, but the ease so obtained gives no cheerful expression to the countenance, such as would be the case in a true healthy resolution. On the contrary, the eyes sink deep into the head, with a lack-lustre stupidity, and are surrounded by a dark-blue ring. The brow is pale, and covered with cold drops of sweat; the cheeks are sunk, the mouth open, the tongue furred brown, and the teeth covered with black sordes; the lips are pale, the whole face is cold, and the body exhales a peculiarly damp earthy odour—the certain precursor of death. Locally, there will be tympanitis, and perhaps some dribbling of offensive matter from the urethra, but the general signs which I have now given will attend the onset of gangrene in any vital part of the body, and our great aim, on every occasion, must be to prevent it.

Chronic Cystitis is no uncommon complaint, especially amongst the old, but is usually associated with other forms of disease which constitute local causes of continued irritation. This may be instanced in scirrhus of the rectum, enlargement and induration of the prostate gland, passage of gravelly matter from the kidneys, and strictures of the urethra, besides foreign bodies or degenerate growths within the textures of the bladder

itself. In such an affection, setting aside the peculiarities of each individual case, according to its peculiar cause—all of which, however, must be diligently investigated, with a view to diagnosis and correct treatment,—we shall have a dull localised pain over the pubes, increased under pressure, along with frequent uneasy micturition, the urine being loaded with mucus or pus, more or less thick and tenacious according to the severity of the disease. Some time ago I had an old man under my care labouring under this complaint to a great degree. He was upwards of 82, and the action had been of about twelve months' standing; otherwise, however, he appeared healthy, nor did the disease seem traceable to any peculiar cause. He suffered much pain from ineffectual attempts to make water very many times in the day. A drop or two only would come, after much straining; and the bladder would still feel full and very irritable. The pulse was not materially disturbed; but he could not sleep at night from the above cause. Once in twenty-four or thirty-six hours he was wont to pass, after a protracted and agonizing effort a quantity of fibrinated mucus, slightly intermingled with pus, so thick and tenacious that on dipping a stick into it and drawing it out, you could thus form a thin rope of it from one end of the room to the other, without its showing any tendency to give way. I found he had been taking nitric acid in sarsaparilla, but without any change in his symptoms. In fact, these discharges, out of the body, were coagulated into almost solid masses like cod sound, by the influence of nitric acid, and the same result might have been expected within the system. It was soluble, however, in potassa, and he therefore took that alkali in an infusion of *uva ursi*, which astringent diuretic is so well known to have peculiar healing powers over the urinary mucous membrane. From that time he began to pass his water more freely, and the mucus ceased to form such tenacious masses within the bladder as I have described. Under these favourable circumstances, however, he began to complain of an intolerable internal itching, so that, as he expressed it, he felt "inclined to tear his bowels out." This I was disposed to attribute to the virtues of the bearberry. Without intermitting its exhibition, however, he had laudanum and tincture of conium added to his draught. These abated the sense of itching, and within one month he had no symptoms of disordered bladder beyond making water oftener than usual. This, however, was also removed after he had concluded his course of potassa and bearberry, by the use of the muriated iron and lytta. He is still living, and I have heard of no return of the malady.

In regard to the special and general treatment of these inflammations, it is to be observed in the first place, that all of them require local abstraction of blood unless they be of very mild form, or the constitutional circumstances of the patient clearly forbid it. Mercury, antimony, and digitalis, will also be of their usual general value, as in other inflammations; but, as the first agent is specially applicable to inflammatory action in the bowels and in the fibrous and serous tissues, the second to a similar action in the lungs and skin, and the third to

acute affections of the heart, so these urinary organs have their peculiar modes of action, which are to be met by peculiar remedies. Thus, in acute nephritis while we would cup or apply leeches over the loins, to such extent as might be necessary, and at the same time give mild oleaginous purgatives along with mercury, we would not expect that decided effect from the latter agent which we look for in affections of the brain, or liver, or bowels, or peritoneum, &c. The kidneys are peculiar glands, which the mercury does not so directly affect, and the great object, therefore, is to relieve them of that burden which they usually bear in the business of excretion, and to lessen the degree of irritation which might be fatally injurious to them in such a condition. This is to be effected by moderating the amount both of solid and fluid ingesta, or, if thirst so prevail as to demand satisfaction, the drinks must be of the most demulcent and unstimulating nature, such as barley or acacia-water. Other excreting organs are also to be solicited to increased activity as a means of relief by a vicarious discharge of the urinary elements. Hence the employment of purgatives, and sudorifics, or diaphoretics, with this view; though it can be effected only under certain limitations, inasmuch as no other glands are calculated fully to take the place of the kidneys in the system. When the acute action is thus subdued, it will be desirable to begin the use of *uva ursi*, or buchu, in combination with an alkali and sedative, such as potass or soda, in alliance with the tinctures of opium or conium. If it be not arrested, however, and an abscess be inevitable, we can only place an anodyne poultice over the loins and leave the result to nature, cautiously watching every turn of the symptoms.

We very seldom have inflammation of the ureters except as an extension of the same action from the kidneys, or bladder; and when it does arise the treatment is the same as in such inflammations. In cystitis, as in nephritis, the first step to be adopted, if the patient can at all bear it, is the local abstraction of blood; after which a blister may be applied over the pubes, for it never, (except in some peculiar constitutions,) causes strangury when placed there, though it often does so if applied over the kidneys. These measures are to be repeated again and again if necessary; but if not actually required, and some pain and irritability remain, we may next resort to a belladonna plaster. While employing these external means, it may also be necessary to use soothing urethral injections, or suppositories of opium by the bowels. Alkalized draughts of *uva ursi*, with conium or opium, are here especially serviceable when the acute action is moderated, and the drinks, which may be taken in any quantity, must, however, be of a very demulcent nature. The decoction of the marsh mallow is very good. If irritability continue afterwards, a belladonna plaster may be worn for some time—till it be subdued, while a tonic course is resorted to, including the use of steel and cold ablutions.

The chronic cystitis is, as already observed, to be treated in the same manner as the declining stage of the acute disease. We are to inquire carefully whether it be due to a stone in the bladder, or to gravel descending from

the kidneys, or to prostatic induration, or any neighbouring disease of the womb or rectum, in each of which cases, if any one of them exist, we must direct our more special treatment to such causes. Thus, in our patient Rebecca Brooks, aged 60, who died of dysentery and deep extensive ulcerations of the rectum, the inflammatory action extended to the bladder and ureters; also in Sarah Binion, aged 40, who died of phagedenic carcinoma of the uterus, and in whom the vagina was a softened purulent mass, and the cervix uteri had entirely disappeared, we also found that part of the bladder which was next the womb in a state of scirrhus, while the viscus was also contracted, and its mucous membrane in an inflamed condition; and such causes will exist in many cases. Some, such as the above, are scarcely impressionable by any means, and prostatic enlargement and induration is almost as bad, though the danger be not so imminent. But if we suspect a stone in the bladder, that is known how to be managed by the surgeon, and if gravel be passed, we must examine its chemical composition, with a view to adapt the remedy to it. These collateral matters being thus duly considered, the local inflammation itself is chiefly to be controlled either by leeches or blisters, according to circumstances, accompanied with the internal remedies already alluded to. The potass would appear to liquefy the tenacious fibrinated mucus, as well as to neutralize any irritating acid elements in the urine. The *uva ursi* and *buchu* seem both to constrict the extreme vessels of this mucous membrane, and so reduce them to a more healthy calibre, while the opium or conium, or any other such sedative, lulls the sensibility, and so renders the parts less likely to be excited by any irritating cause. The outlines of a case of this kind I have already given to you, in that of the old man; they are rather common amongst such elderly persons, though not usually so severe as the one I have described. In all of them, it is highly desirable that the concluding part of the treatment should consist of a course of steel and cantharides, as no other combination seems to have such a tonic effect upon the urinary mucous membrane. I must defer the consideration of congestions and degenerations in these parts till my next lecture.

CASES OF DIFFICULT PARTURITION.

By EDWIN BISHOP, Esq.,

For some years Assistant-Surgeon to the West London Union, and Greenwich Union Infirmary.

DURING twelve months' engagement with L. Owen Fox, Esq., of Broughton, Hants, the following cases of midwifery, (with a great number of others) fell under my care; should you consider them of sufficient interest to occupy a space in your valuable journal, you will oblige me by inserting them.

For some months in succession it was remarked by Mr. Fox that I had what might with some truth be termed a run of ill luck, for almost every case was

either tedious, complicated, or preternatural, and perhaps it will not be considered out of place here to observe the difficulties the *rural* surgeon has to contend with compared to practitioners in or near large towns; the former is almost compelled to depend on his own professional experience, whereas the latter can obtain the benefit of a second opinion without loss of time or trouble.

Dr. Ramsbotham, in his very excellent work on midwifery, makes the following observations in reference to cases requiring instrumental aid:—"As soon as a necessity for instrumental interference appears, two questions of some importance will naturally offer themselves to our mind—the first, whether we shall call in the assistance of another practitioner to advise us by his council, to aid us in the operation, and to divide with us the responsibility of the case; and the second, whether we shall apprise the patient of the necessity of such help, and obtain her sanction and approval." Every practitioner will, I doubt not, admit the necessity of this, and if necessary and convenient seek further aid, when combating difficulties dangerous to his patient, and with his own reputation at stake.

CASE I.

Mrs. G., aged between 40 and 50, living at Winterslow, the mother of eleven children, states she has required "extra" assistance on the part of her medical attendants in several confinements; has had adhesion of the placenta, and preternatural presentations; always had "hard labours," and much dreads this being a difficult time. I reached her house soon after seven, A.M., found the pains very strong and regular, accompanied with "a show," which had marked the floor of the room in her passage to and fro. Had been in labour several hours. The os uteri dilated, the head presenting and entering the vagina, parts moist and yielding; bowels relieved twice during the night; has passed water several times.

In less than two hours after I had reached her house the head had so far advanced as to press against the perineum. In this case—a woman who had previously given birth to nearly a dozen children, I naturally thought to be released quickly. In another hour the pains relaxed a little; I gave her two full doses of the æthereal tincture of ergot, and waited; the uterus was roused from the second draught, the pains continued strong again, and at regular intervals, but there was no further prospect of labour being safely completed by the natural powers. Having now remained with her for a considerable period, without any marked improvement, and fearing rupture of the uterus, (for it was remarkably distended) together with the fear and anxiety of the patient and relatives about her, I despatched a man on my horse for the forceps; he had to ride nearly ten miles, which occupied another hour.

Considering that this poor woman had passed through similar trials, I never met with a case where fear and mental depression were so prominent; kind words and promises of a favourable issue failed to inspire her with hope. Having received the forceps, I at once

commenced the operation. Both ears could be felt distinctly, and in that position considered the most favourable to admit of the child's exit. I placed her at the edge of the bed, and used the necessary precautions. I succeeded in locking the forceps after some difficulty and perseverance, and with a few extractive efforts, making pressure of the blades at the same time, the head moved forward. She was delivered at four P.M., much exhausted. The child was born alive and weighed eleven pounds some few ounces. After expulsion of the placenta she had considerable hæmorrhage, which was arrested before I left the house. Her progress to convalescence was speedy. The child lived over a week and died of jaundice.

CASE II.

Mrs. P., aged 30, in labour with her first child, residing at Lockerley, summoned me on a Sunday evening, about seven o'clock. She is a short, thick-built person, something after the style alluded to by Byron in "Don Juan," "a dumpy woman." Reports that pains commenced in the previous night, and have continued at regular intervals, and without intermission, to this time; from the commencement has had no sleep, and feels much tired. At nine the os uteri was dilated to about the size of a crown piece, thin at the edges, and yielding; membranes entire; head presenting. As I was five miles from home I decided upon remaining with her, with more comfort to myself than to my horse, who was exposed to the winds in an open shed. By daylight the head was in the vagina, and at eight, A.M., pressing against the perineum, the pains appeared quite strong enough to expel the child, but it did not come. I carefully avoided frequent examinations, fearing she would require instrumental aid in some shape. Warm applications were directed to be applied to the vulva and perineum, with the view of relaxing the parts, if possible. The room was kept cool and quiet, and proper drinks administered. The pains began to lose their wonted vigour, still I hoped it would eventually be over without any interference on my part. I had now been in the house seventeen hours. No progress in the last four hours, and the pains were dwindling into nothing, evidently from want of power. She was much exhausted, and disagreeable progressive symptoms were stealing upon her. It became necessary that she should be delivered with the aid of the forceps, if possible, without further delay. The os externum appeared smaller than usual. Probably her age (30, and the first child,) militated against the parts giving way. With considerable trouble and difficulty I passed the first blade, the second glided tolerably easy. She was delivered, after much care and patience, about three, P.M., twenty hours from the time of my arrival. The perineum was slightly lacerated. The child was full-sized, born alive, but died soon after. The mother down stairs in about ten days.

CASE III.

I was sent for one evening to Mrs. P., of Lower Wallop, in labour with her fourth child, under the care

of an old midwife. She had been in labour since the morning. Much excited, irritable, and highly nervous. Upon examination I found the left hand in the vagina, which the midwife had mistaken for a foot, and who said she "couldna' tell why the child didna' come, as the pains wur strong."* The membranes had been ruptured some hours. Pains very violent. I gave her a full dose of tincture of opium, which quieted her, and proceeded to turn. I passed my hand, and succeeded in getting back the arm, after several attempts. The right elbow could be felt, and also the right knee, which I hooked down. With the knee there was a portion of the funis, without pulsation. The breech passed easily, and labour was completed, satisfactorily, in about two hours. The child was still-born, rather above the average size; its left hand and arm considerably swollen, and very livid. The placenta followed quickly.

[To be continued]

EFFECTS OF IODINE ON THE MAMMÆ,

BY JOHN M. BRYAN, Esq.

ELIZABETH MARLOW, aged 16, of robust healthy appearance, had menstruated regularly for more than twelve months; was very fat generally all over the body, and with very large mammæ for her age; applied to me January 12, 1836, for relief of bronchocele, there being great enlargement of the thyroid gland, both in front and at the sides, causing considerable uneasiness from pressure upon the adjacent parts. She commenced using Unguentum Hydriodatis Potassæ, rubbed into the swelling for fifteen minutes every night, taking inwardly at the same time five drops of the compound tincture of iodine three times a day which treatment she persevered in until March 14, when she commenced applying the tincture to the swelling night and morning, instead of the ointment.

This treatment was continued until April 23, when she began to suffer from giddiness and defective vision, and left off the iodine both internally and externally, as it was evidently affecting her health, the flesh losing its firm feeling and appearance, and she was becoming altogether out of health, and was placed under other treatment, having reference to her particular condition, in June and July, consisting of effervescent saline medicine, with alterative aperients. Nevertheless, she gradually became thinner, so that towards the end of the year the mammæ were quite wasted away, and there was a general wasting of the whole body, tending to the supposition that she was in a rapid decline, the bronchocele had also wasted very considerably, although not so

* The old midwife under whose care this case fell, was then upwards of eighty years of age. Her faculties were clear, and good, and she often boasted to me of having "followed the art," (as she quaintly designated it,) and of having attended several hundred cases. We may, therefore, fairly infer, she has deprived the local medical officer of many hundred pounds.

much in proportion as other parts. In the beginning of 1837, under a restorative plan of treatment, she gradually altered for the better, and became again in a few months quite *enbonpoint*, and so she has remained until the present time. The bronchoecle enlarged also, and is now much the same as at the commencement of the treatment.

Northampton, March 16, 1852.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CASES

Reported under the terms proposed by the Association.

BY OBSERVATOR.

Case of Pleuro-Pneumonia complicated with Tubercle.

THIS case, in which it was obvious that pleurisy and acute pneumonia existed, forcibly illustrates the importance of ascertaining the previous history of a case. In this instance, the only symptom of tubercle was an old-standing cough; where the acute complications have produced organic changes, of course an accurate diagnosis is rendered extremely difficult.

History.—Frederick Farmer, aged 42, of *nervo-sanguineous* temperament, became an in-patient of the Queen's Hospital, Birmingham, under Dr. Nelson, on the 2nd of December, 1850. He stated that he had been subject to cough for some years, and that a fit of coughing usually occurred every morning. About a fortnight previous to admission, after violent exertion, he was seized with a dry harsh cough, with chilliness and difficulty of breathing, which came on in the night, but did not observe that the expectorated matter was at all discoloured. He was attended, expectorants were administered, but he became worse and was sent into the hospital.

Symptoms.—He now complained of severe dyspnoea, which was increased by the slightest exertion, with dull pain on inspiration. His cheeks were flushed, and during the last five days his legs had swollen. Expression of countenance intensely anxious, absence of the respiratory murmur, and of the local thrill in the lower part of the left lung; also complete dullness under percussion. On the lower portion of the right side there was marked crepitation, and hasty bronchial respiration above. Pulse 96; respiration 50.

Diagnosis.—Pleuro-pneumonia with effusions.

Indications.—To subdue inflammatory action and promote absorption.

Treatment.—Calomel was ordered, every two hours, and tartrate of antimony with hyoscyamus, every hour; and a blister was applied to the chest. On the following day his spirits were a little higher, but scarcely any

change had taken place. Pulse 116; respiration 56. He gradually sunk and died on the 4th.

Post-mortem appearances.—The left lung had collapsed to about half its natural size, and in the left plural cavity was a large quantity of whitish serum, several adhesive bands stretched across from the lungs to the pleura, and there were large flakes of fibrinous lymph in the lower part. There was also a small excavation at the apex, containing disintegrated tubercle. The right lung was gorged with blood and the lower portion was in the first stage of acute pneumonia.

Observations.—It seems probable that tubercle had been deposited in the apex of the left lung, which became softened, under the continued irritation of a neglected cough. Ultimately, as is frequently the case, acute pleurisy supervened, which not being actively treated, proceeded to effusion, causing collapse of the left lung. The burden of the circulation falling on the right lung alone, engorgement and inflammation followed, and death ensued. A timely abstraction of blood might have been beneficial, but in the sinking stage, would have been useless.

Case of Frontal Neuralgia.

IN reference to this complaint, it may not be out of place to remark that neuralgia, chronic rheumatism, spasms, and some nervous affections, may be and are sometimes made subjects of simulation and pretence, in order to obtain comfortable board and lodging, and thus impose upon charitable institutions. Where there is reason for suspicion, the application of setons and blisters, with brisk purging and low diet, generally proves an efficient test of such pretensions. The simple and consistent account given by the patient in this case, his early report of relief, and general conduct, left no doubt of the truth of his complaint.

Matthew Chambers, aged 24, of *nervo-lymphatic* temperament, was admitted an in-patient to the Queen's Hospital, under Dr. Nelson, on the 14th of December, 1850.

History.—He stated that his general health had been tolerably good, but that for some months he had been afflicted with acute shooting pains. Purgatives and liniments had been employed, but to no purpose.

Symptoms.—The pains which were limited to the left side of the forehead and left temple continued. The urine contained large quantities of lithates and the bowels were costive. Pulse 88, steady.

Diagnosis.—Local neuralgia.

Indications.—To improve the secretions and diminish the local sensibility.

Treatment.—He took pills of mercury and colocynth every night, and a colchicum pill with an alkaline diuretic draught thrice a day, and a belladonna plaster was applied over the left eye.

On the 17th, the bowels and kidneys acted freely, and only occasional slight twitches of pain. Continued the medicines.

On the 21st the pains were very slight; the urine clear and tongue clean. He continued the aperient

pills every night, but omitted the colchicum and diuretic draughts, in lieu of which full doses of carbonate of iron were administered.

On the 28th the pains had quite gone; urine clear and plentiful, and he felt quite well.

On the 31st there had not been any recurrence of symptoms, when he left the hospital. He was advised to keep the bowels open and continue taking the iron, with small doses of carbonate of soda, for some time. The beneficial results of the treatment so speedily obtained in this case afford a strong proof of the peculiar efficacy of colchicum and iron in neuralgic affections.

CHELTENHAM GENERAL HOSPITAL.

CASES

Reported under the Terms proposed by the Association.

BY OCULUS APERTUS.

Fracture of the Ilium through the Acetabulum.

WILLIAM BENNETT, aged 52, was admitted into the Cheltenham General Hospital under the care of Dr. Eves, August 5th, 1850.

As he was riding down hill on a velocipede, at a very quick pace, the machine fell, and he was thrown violently on his right side.

Present Symptoms.—He feels severe pain in moving the right lower extremity. The right anterior superior spinous process of the ilium projects considerably, and the skin covering it is very red and tense. By moving the limb, the head being placed on the ilium, a decided crepitus may be felt.

A bandage was placed round the pelvis, and a long splint applied to the limb. Nothing more occurred worthy of record. On September 9th, the splint was removed, and the bone was found to be completely united. He was ordered to rub the hip with the following liniment:—Lin. Vol., oz. j.; Tinct. Opii, oz. ss. *M. Fiat linimentum sœpe applicandum.* The joint gradually regained its strength, and he left the hospital cured, with the full use of his limb.

Dr. Eves remarked that this was the only case of fracture of the pelvis which he had seen recover, as this accident is generally caused by a crushing weight falling on the part, which, besides fracturing the bone, produces also some other internal lesion, such as rupture of the bladder, or severe injury to some of the abdominal viscera. The peculiar manner in which the accident happened in Bennett's case, explains the recovery. The long splint was used to prevent motion of the limb, by which the fractured part of the bone would have been moved, by means of the head of the femur acting on the acetabulum. Sir Astley Cooper records three cases of recovery from simple fracture of the os innominatum, and one from compound fracture.

Compound Fracture of the Skull.

HENRY PREECE, aged 25, was admitted into the Cheltenham General Hospital, December 25th, 1851, under Dr. Eves. About half-past seven this morning he received a kick from a horse on the right side of the head. He was brought into the hospital at half-past nine.

On examination there was found a wound of the scalp, about four inches in length, commencing over the right parietal bone, and extending across the parietal suture to the opposite bone. The skull was fractured, and a portion of bone driven in, for about three inches in length; both tables of the bone at the right extremity of the fracture were broken, so that a probe might be passed between the outer table of the depressed portion and the inner table of the bone, which remained in its natural position. The left extremity presented a deep furrow. He was quite sensible, and as there were no symptoms of compression, the wound was simply brought together by sutures. To have low diet.—R. Hydrarg. Chlor., gr. v., statim et habeat haustum aperientem post horam.—R. Ant. Pot. Tart., gr. ij.; Mist. Camph., oz. viij. *M. Uncia dimidia tertiis horis sumenda.*

Half-past nine, P.M.—He had vomited frequently for about an hour after his admission, and now complains of a severe pain in his head.—*Venæsectio ad oz. xij.*

26th.—Pulse 81; tongue clean; pain in his head removed; no bad symptoms.—*Cont. Mist. Ant. Tart.*

28th.—No bad symptom; to-day he says that he does not remember anything either of the accident or of being brought into the hospital.—Low diet, and *Mist. Ant. Tart.* to be continued.

The antiphlogistic regimen was strictly enforced for nearly three weeks, the tartarized antimony being gradually lessened, and no bad symptom having supervened, he left the hospital on the 26th of January quite well.

Remarks.—Some difference of opinion still exists respecting the treatment of compound fracture of the skull, *with depression*. It must be considered that the operation of trephining is of itself often sufficiently dangerous to produce death; in proof of this I would adduce the following quotation from Mr. Ellis's "Lectures on Clinical Surgery," p. 139:—"The late Dr. Colles was in the habit of stating in his lectures, that about sixty or seventy years ago there was a Dr. E—t in this city, who fancied that insanity was often the consequence of a want of due proportion between the size of the brain and the cavity of the cranium, in short, that the brain had not sufficient room to perform its functions, and the consequence was madness. He accordingly persuaded himself 'that if there was a large hole (a foramen magnum superior) made in the roof of the skull, that it would be productive of the double advantage of relieving the brain from the undue restraint imposed on it by the comparatively small size of the skull, and of admitting at the same time the

fresh air to cool the overheated organ.' Strange as it may appear, this doctor was allowed to test the validity of his theory in Swift's hospital; and the surgeon of the institution, Mr. O—e, with more condescension than humanity, trepanned three unfortunate patients! Well then, the brains of these poor creatures were relieved from the imaginary restraint which the sapient Doctor, in the sublimity of his hallucinations, thought they suffered, and the cool air was admitted, (aye, and the light, too,) but with what effect? I have the authority of Dr. Colles, when I state that no advantage whatever resulted from the operations; on the contrary, two out of the three persons operated upon died of inflammation of the brain and its membranes; the third survived, having suffered only from the pain of the operation and permanent deformity! What a cruel and disgusting piece of absurdity from beginning to end. The only rational way of accounting for the transaction, is by supposing that all the parties concerned were in a state of mental derangement. The doctor and the surgeon were certainly the most dangerous lunatics I ever heard of."

Nothing, then, but absolute necessity can justify this operation. As, therefore, there were not any symptoms of compression in this case, Dr. Eves determined merely to treat it strictly upon antiphlogistic principles, and the result proved the propriety of his decision. Mr. Ellis rather inclines to the doctrine, that in compound fracture, *with depression*, in adults, although the constitutional symptoms are trifling, the depressed bone ought to be elevated before the wound is dressed. Sir Astley Cooper held the same opinion.

Compound Fracture of Femur; Simple Fracture of Humerus; Dislocation of Shoulder.

JOHN WEBB, aged 55, was admitted into the Cheltenham General Hospital, under the care of Dr. Eves, April 16th, 1851. Compound fracture of the right femur in the middle-third, with small external wound; simple fracture of the right humerus at its upper-third; dislocation of the same bone upwards and forwards, the head of the humerus being distinctly felt immediately below the clavicle.

He is an agricultural labourer, of a healthy aspect, and has always enjoyed tolerable health. This morning, as he was examining the axle-tree of a loaded dung cart, it (the axle-tree) broke, and the cart fell on him, and remained on him for about two minutes before he could be extricated. Splints were applied to the thigh, and an attempt was made to reduce the dislocation, but failed on account of the fracture of the humerus being too near the shoulder to admit of sufficient hold being obtained to make the requisite extension. Splints were applied to the arm, with the hope that the dislocation might be reduced after the bone had become properly united.

May 14th.—The discharge of pus, which commenced a few days after his admission, has now become very profuse, and exceedingly foetid. There is no

attempt at union of bone, and he is evidently sinking. Amputation, by circular incision, was therefore performed at the upper-third of the thigh. The muscles in the centre of the stump presented a dark unhealthy appearance.

17th.—Stump dressed; no union; foetid discharge. Warm water-dressing ordered.

20th.—Stump in a sloughing state, with very foetid discharge.

24th.—Stump healing, with healthy granulations.

June 4th.—Tongue brown, and dry; vomiting.—R. Hydrarg. Chlor., gr. iij.; Pulv. Zingiberis, gr. j. M. Fiat pulv. statim sumendus.

9th.—The wound is much contracted; all the ligatures but one are removed; his back is red and painful.—Ordered to be bathed with spirits of camphor, and the patient to be placed on a *water bed*.

11th.—His back is much better.—R. Mist. Quinæ, oz. j., bis die.

18th.—All the ligatures are removed; the stump is healed, except over the bone, the edges of which project through the granulations. The strapping hitherto employed has been to-day discontinued.

July 5th.—For the last two or three days the stump has been swollen; he has been flushed, and had rigors; to-day an abscess has burst in the stump, appearing to communicate with the back, discharging, as Mr. Hartley, the resident medical officer states, about *half a gallon of pus*.

7th.—He appears sinking rapidly; there is a collection of matter between the fascia and integument, occupying the whole of the left back, but not appearing to communicate with the opening in the stump, although doubtless the whole of the integuments of the back formed at first the wall of an immense cavity, containing pus. This abscess was punctured, and about half a pint of thick pus discharged. A piece of lint was placed in the opening, to prevent its closing. Tongue clean; pulse 90.—Cont. Mist. Quinæ. Haustum anodynum habeat, horâ somni sumendum.

8th.—Considerable discharge on withdrawing the plug; tongue clean.—Repetatur haustum.

12th.—Discharge copious; pulse 120.—Cont. Mist. Quinæ.

18th.—Discharge about the same; tongue clean; appetite good.

21st.—Edge of bone somewhat projects; appetite good; tongue clean; discharge greatly diminished.

28th.—A small half circle of bone has exfoliated; discharge from the stump and back has quite ceased.

August 4th.—Matter having again formed between the integument and fascia of the back, an incision was made, and pus, to the amount of a pint and a half, escaped.

12th.—Discharge from back copious.—R. Mist. Quinæ, oz. j., ter die.

September 6th.—Back still discharges slightly; the stump has healed, and looks well.

22nd.—Left the hospital cured. The dislocation of the humerus remaining unreduced, for taking both the debility of the patient and length of duration of dislo-

cation into consideration, Dr. Eves did not think proper to attempt its reduction.

This patient, who resided several miles from the hospital came in on January 14th, 1852, to have a wooden leg made; during his stay he became much flushed in the face, there was pain, redness, heat, and swelling of the stump, and in a few days an abscess burst in it, which, after discharging for a few days, got well, and he again left the hospital apparently cured, but of course not able to wear an artificial leg. It is right to state, that besides the quinine, &c., Webb was supported throughout his illness with good diet and porter. The case is a remarkable instance of recovery from a severe accident followed by such enormous suppuration. The amputation was performed under chloroform which saved the system that additional shock and doubtless greatly assisted his recovery.

On examination, the broken ends of the femur were found completely denuded of the periosteum to a considerable extent, and the muscular tissue in the vicinity of the fracture was of a dark colour, softened, and surrounded with pus.

Provincial Medical & Surgical Journal.

WEDNESDAY, APRIL 28, 1852.

THE records of the conduct of the medical officers of both services, so almost universally represent them in a favourable light, that let the circumstances under which they may be placed be ever so difficult or dangerous, we look for details of unflinching devotion to duty and to the dictates of humanity as a matter of course. It is, therefore, with a feeling akin to shame, that we meet with any instance which is calculated to prove an exception to the general rule, such as at first sight appears to have been the conduct of the assistant-surgeon of the ill-fated vessel, *Birkenhead*. If we are to put any faith in the narrative of one of the survivors of this catastrophe, as quoted in the "Leader" of the *Times*, the assistant-surgeon was the indirect cause of the destruction of many unfortunates, he having, with eight of the crew, hurried away to shore at once, without heeding the shrieks of numbers who were struggling in the waters around him. We do not hesitate to repudiate such an interpretation of the circumstances, and cannot avoid the conviction that the *Times* is deserving of censure for so prematurely blasting the character of a gentleman, who, as it may turn out after all, acted to the best of his judgment, under the

awful trials to which he was exposed. Until we have better authority at least than this, we will not believe, that while officers and men were offering an example of self-sacrifice, unparalleled in the annals of heroism, the surgeon alone could slink away to shore, bent only upon the preservation of a life which universal execration, he might feel assured, would render a burthen to him.

We had penned these few lines, when with the greatest satisfaction we found our surmises more than justified in the manly remonstrance of a relation of the maligned assistant-surgeon. So far from being among the first to seek safety, Mr. CULHANE was *the last* to leave the sinking ship, and only as the poop on which he stood, sunk in the waters beneath his feet, did this noble fellow strive to preserve his own life, which he did not easily, but by swimming *more than a mile* to reach the boat in which he is said to have escaped. Nor is this all: after vainly attempting to save others, and for a period of ten hours, being exposed to wet and fatigue in an open boat, he rode a distance of *ninety-five* miles without rest, in the humane attempt to obtain the most available help. If ever reparation was due to a calumniated man, the *Times* owes it Mr. CULHANE, and it will but do him but half justice if it does not own him to be a man of whom, not only his profession but his country must be proud.

THE probable operation of the proposed New Pharmacy Bill seems to excite less attention among the members of the profession in general practice than might have been anticipated. And yet its objects should be anything but a matter of indifference as regards the immediate interests of this important class of practitioners. The intention of the bill is clearly to raise the status of the chemist and druggist—to metamorphose him, in fact, from a mere drug grinder to a scientific pharmacist. To this no valid objection can be raised, abstractedly considered; on the contrary, it is much to be desired, that so important a duty as that of dispensing, should be discharged alone by men whose competence as to their knowledge of the properties and doses of drugs has been properly tested; instead of, as at present, being intrusted to any one who chooses to invest his capital in blue bottles and a smart mahogany counter. There is, however, a

view of the question which shows that what is desirable in one respect may be detrimental in another, and this is the operation of the Bill on the functions and interests of the surgeon in general practice. To us it appears more than probable, that these interests will suffer considerable damage in the event of this Bill becoming law. Already their legitimate sphere is shamefully encroached upon, even with the minimum of knowledge the druggist can pretend to; and we are much mistaken if then the domain of the general practitioner be not still more seriously invaded. The humbler classes even now too often fail to perceive the inferiority of the druggist to the educated and diplomatized surgeon; will not the confusion in their minds be still greater, when the former can exhibit a parchment, which, to their uninstructed eyes is just as showy, and therefore equally a test of skill as that of the Apothecaries' Hall? That the effect of the Bill will be to exalt the chemist at the expense of the general practitioner we do not doubt, unless some stringent clause be introduced with reference to prescribing across the counter; and this clause it behoves the general practitioner to strive for, if he would preserve his legitimate sources of emolument from still further diminution.

Since writing the above we have received the letter of Dr. WEBSTER, published at page 228. This gentleman takes the same view as ourselves of the proposed Bill; and we cannot avoid drawing attention to the plan which he advocates for opposing the measure in Parliament. Something of this nature should assuredly be attempted, and we do not see how we can improve upon Dr. WEBSTER's proposition.

There is one suggestion, too, that we would make to the framers of the Bill, which would at least have the effect of popularising the measure to a certain degree with the medical profession; and this is, by some means to disconnect the compounding and dispensing of drugs from the vending of quack medicines. Such is the extent to which these villainous nostrums are sold, by chemists of even the most respectable standing, that the latter are really less the adjuvants of true medical science, than of fraud and imposture. If Mr. BELL has the true advancement of the pharmacutists at heart, he will make a strenuous endeavour to purge his order from this damning blot, and leave the distribution of all the farrago of quackery to hungry newspaper

proprietors, a class of individuals who think there is no inconsistency in reviewing a book of sermons in one column, and advertising the most beastly obscenities in another.

Reviews.

Neuralgia; its Various Forms, Pathology, and Treatment. Being the Jacksonian Prize Essay of the Royal College of Surgeons for 1850, with Additions. By C. TOOGOOD DOWNING, M.D., M.R.C.S. London: Churchill, 1851.

WHILE we do not attempt to reply to the inquiry,—Why it is that disorders of the nervous system are so much more prevalent now than heretofore, there can be little difficulty in acknowledging the fact, as well as in applauding the choice of Dr. Downing in making a most important section of these disorders the theme of his essay.

Neuralgia is a term generally understood to express a pain in the track of a nerve, unconnected with inflammation or recognisable lesion. The character of the pain is familiar to all practitioners, and is diagnosed by intermittent paroxysms, variously described as plunging, stabbing, tearing, or shooting, confined to the immediate locality of a known nerve and its ramifications. Dr. Downing divides neuralgia into three varieties, the spasmodic, rheumatic, and hysterical; each of which admits of further subdivisions, according to the site of the nerve affected. *Spasmodic* neuralgia is thus described:—

"The attack is sudden, instantaneous, and usually without warning. A person in good health is seized in a moment with violent pain in some part of the body. He cannot account for it. The suffering is perhaps moderate at first, and ceases in a few minutes. It then recurs after a brief space, again without warning or apparent cause, and increases in severity and duration. Ultimately the disease is fully established; the suffering occurs at intervals, and often amounts to paroxysms of excruciating agony. Then it is that some premonitory symptoms may be noticed before the attack, and an exciting cause may often be evident. But the patient alone is sensible of the approaching fit. Nothing can be detected by the medical attendant to indicate it, either on the part or in general demeanour, except, perhaps, a little more watchfulness in the countenance. The patient

is on the alert,—is roused by some indefinable internal sensations. * * * * From careful inquiry I have ascertained that the usual process is this,—the previous fit having passed off, the nerve has an interval of rest. It sleeps, as it were, to recruit its exhausted strength. When this is effected, indications are given that it is prepared for renewed action. * * * * The parts previously relaxed in rest begin to brace up, so to speak. They assume a state of great excitability. Slight painless shocks are experienced; and these are succeeded by others of gradually increasing intensity, until the paroxysm is fully established.”—p. 7

The character of the pain is various; in some (and we can speak from painful experience) it resembles repeated electric shocks, each for a moment followed by an agonizing vibration, apparently of the nerve fibre itself. Others describe it as “burning,” “pricking,” “throbbing,” &c. The paroxysms are intermittent, though grouped together for a few hours at intervals of minutes. In some cases a distinct periodicity is observed. This, the author regards, and we think justly, as a favourable element in the case. Much diversity is known to exist in the direction of the pain, as well as in the extent of nerve affected. Generally, the author observes, that the pain darts from within outwards; but the reverse is occasionally the fact. Sometimes a spot which can be covered with the finger is alone painful, at others the pain will radiate from this as from a centre. Great difference also exists in respect of the tenderness of the affected part. In some the lightest touch,—as of the clothes, will reproduce the agony; in others, relief is obtained by firm pressure. The course and termination are as various as the symptoms.

Rheumatic neuralgia is marked by heat, pain, and tenderness of surface; and the pain, according to the author, is more constant and dull than in the former variety, although there are intervals of exacerbation. It is also to be traced mostly to cold. The author, however, admits that the diagnosis is difficult in words, though facile in practice.

Hysterical neuralgia is another of the many phases of hysteria, which is saying but little, for what is hysteria? Its most usual situations are the head, as in *clavus*; below the *mammæ*, in the *iliac* regions, *loins*, *sacrum*, or *spine* generally; in the *mamma*, or one or other of the joints.

With this brief description of the varieties of

neuralgic pain, Dr. Downing next proceeds to the consideration of the causes, predisposing and exciting. Amongst the former are age, sex, mode of life, and hereditary predisposition; the latter, according to the author, is more potent than is generally admitted. He thinks “there cannot be a shadow of doubt that the neuralgic diathesis and even special forms of the affection are occasionally derived from parentage.”

In speaking of the exciting causes, Dr. Downing enters with some minuteness into the rôle of the alimentary canal in its deranged conditions. The exact influence of these has been disputed, but the facts in favour of the hypothesis are too numerous to be easily disposed of. In our own personal experience, violent attacks of *sciatica* are indisputably traceable to dyspeptic troubles. There are, however, many cases in which dyspeptic symptoms, coexisting with neuralgia, may, in the author’s opinion, be the sequence, and not the cause, depending on the irregularity with which food is taken in consequence of the agony which attends mastication. The first relation of the symptoms is only to be made out by careful inquiry into the history of the case. Changes of temperature, osseous deposit in the vicinity of nerves, disease of the nervous centres, caries of the teeth, and malaria, are so many other recognised exciting causes, all of which meet with due consideration.

The proximate cause or nature of neuralgia is involved in obscurity. The author investigates, with great attention, the various theories which have been advanced, and scrupulously weighs the arguments by which each is supported, but without arriving at any very satisfactory conclusion, as is seen in the following quotation:—

“It would be useless to pursue this subject further; a sufficient number of facts have been adduced to justify us in concluding that the nature of neuralgia is not to be discovered by morbid anatomy. In a very small proportion of cases only have alterations been perceptible, and these of a very diverse character; even these were far from pertaining to the nervous affection, but were referrible to neuritis or rheumatism. Moreover, it is proved by an abundance of facts, that neuralgia can exist, with severity, for a number of years without leaving any appreciable lesion after death; we must therefore discard, as unfounded on observation, all those theories which attribute neuralgia to an inflammation, acrid irritation, hypertrophy, or atrophy of nerves. There is reason to regret that no inves-

tigations on this subject have been made with the microscope, as possibly some structural change would be detected which escapes the unaided eye. But with our present information everything tends to demonstrate that this painful malady consists in a functional derangement, the organic cause of which eludes us completely."—p. 80.

The local condition of the nerve during a paroxysm of neuralgia is a question of the utmost interest. Dr. Downing is inclined to the belief that the sensitive fibres are themselves thrown into a state of spasm, through the agency of the neurilemma, a structureless membrane identical with the sarcolemma of unstriated muscular fibre. This idea is not confined to the author, however, as Sauvages had long since adverted to it; and the same opinion is entertained by Mr. Joseph Swan.

We shall not follow our author through the next section of his work, which is occupied with the diagnosis and the alliances of neuralgia with other morbid states, but shall proceed at once to the chapter on treatment, because in this we find the most original portion of his observations.

The principles of treatment in neuralgia are divisible into three indications:—1st, to remove the predisposing and exciting causes; 2nd, to avoid all possible sources of irritation; 3rd, to allay the morbid irritability of the nerve itself. In fulfilling the first indication, the author gives judicious instruction on the method of conducting an examination with reference to the causes, constitutional and local, the removal of which is the *desideratum*; but the third is that on which most is to be said. The medicinal agents are general and local; the former are very numerous, and include drugs of the most opposite actions. Carbonate of iron, quinine, arsenic, zinc, strychnine, among the tonics; croton oil and other purgatives, opium and its preparations, belladonna, aconite, and Indian hemp, among sedatives, form the staple of internal treatment. The local measures, are blisters and other forms of counter-irritants, (which are almost universally employed by Valleix,) veratrine ointment, and the endermic use of morphine and other sedatives, galvanism, intense cold, and lastly, a method peculiar to the author, which we shall presently mention.

In reflecting upon the action of these several remedies, both general and local, the author observes that they may be resolved into two

categories, the stimulant or tonic, and the sedative. Why the same result should follow measures so opposite, he endeavours to show by a reference to the physiology of the nervous system; "both, (he says,) produce the like result,—namely, temporary loss of the polar or erectile property, but in an opposite manner. The one directly paralyzes the action, the other destroys it by over-stimulation."

The new method of treatment to which we allude, as the most original portion of this work, is that of the local application of sedative vapour by means of an apparatus specially adapted to the purpose, and which in the author's hands has been productive of very beneficial results. We do not know that it has been tested by others. The apparatus consists essentially of a reservoir or chamber, in which the material used can be ignited; bellows, for the purpose of generating a current of air through the ignited material; and tubes, with terminations of various kinds, for conducting the air or vapour to the part required. The materials used are chiefly the slender stalks, leaves, and seeds, of sedative plants, such as henbane, hemlock, belladonna, aconite, Indian hemp, &c.

The general doctrines of neuralgia, together with the general principles of treatment, being thus disposed of, the author next addresses himself to the consideration of the local manifestations of the malady, as it shews itself in neuralgia of the several branches of the fifth pair, of the seventh pair, the cervico-occipital, intercostal, lumbo-abdominal, and brachial nerves. Sciatica and crural neuralgia are next in succession, after which we have a description of neuralgia, as it affects the mammae, the testes, the joints, and internal viscera. A very important variety of the disease, *traumatic* neuralgia, occupies the closing chapter of the book. From all these different subjects we might select passages of great practical value, did our space permit; but we are constrained to content ourselves with a notice of the latter form of the disease, which is the more deserving of attention that it has not hitherto been minutely described.

Traumatic neuralgia is the term applied to neuralgia arising from local injury, or, as is not uncommonly the case, from surgical operations. The causes which give rise to this form of neuralgia are stated to be—1st, a foreign body in the substance of the nerve; 2nd, partial or

entire division of a nerve; and 3rd, pressure on a nerve. The author quotes a remarkable case of the first division, which occurred in the practice of Mr. Wardrop; but the most interesting cases are those which occasionally follow amputation, and which are as severe as they are unmanageable. In these cases it is somewhat uncertain whether the pain is to be referred to division, irritation by spiculæ, or to pressure. The author thinks that the pain may be due to either cause; it may arise "from a *fixed half-cut* nervous fibril, which is excited to action by the motion of the limb; from a nervous trunk or fibril *compressed* by the contracting cicatrix, or against the shaft of the bone; or by the hardening of the lymph in the bulbous extremity; and lastly, through *spiculæ of bone* running into, or osseous deposit taking place in, a nervous branch."

In the treatment of traumatic neuralgia no fixed rule can be laid down. Internal remedies are useless; division of the nerve above the presumed seat of irritation has succeeded in some cases, failed in others. The author very properly remarks, that to be successful the division should be practised early, before the nervous system is irretrievably impressed. In neuralgia of stumps, it has been recommended to reopen the cicatrix, remove the bulbous end of the nerve, or to amputate above. The probability of either of these measures being successful will, the author observes, depend on the local nature of the exciting cause, and the localization of the neuralgic pain. His own suggestion is, to rectify, if possible, the general neuralgic diathesis, and to apply local sedatives by his apparatus. In one case narrated, this plan was eminently successful.

We here close our notice of Dr. Downing's volume, and have much pleasure in commending it to the perusal of our readers. The diseases treated of, which are among the most distressing to the patient and baffling to the physician, have, in the present instance, met with an attentive consideration which cannot fail to impart valuable information even to the best informed. Of the probable advantages of the "Aneuralgicon" we will not hazard an opinion, but it is a point upon which experience will soon and readily decide; should it do so favourably, Dr. Downing will have earned himself a most meritorious distinction.

Legal Examiner and Journal of Medical Jurisprudence.

THIS periodical, which is the weekly organ of the movement now going on for the reform of our law, devotes one portion of its pages to the consideration of forensic medicine—a branch of science which has never yet been represented by any English periodical publication. On the Continent and in America there are regular journals which take cognizance of this subject; and we can hardly doubt that an attempt to obtain for it a footing in this country will meet with support from the medical profession. We see that the pages of the *Legal Examiner* contain many interesting medico-legal cases reported from the late circuits; but we believe that the Editor feels the want of some continued support from medical men in the way of contributions on the various points connected with forensic medicine.

A series of papers has, we see, been commenced in this journal on the laws relating to the medical profession. The review goes back to the earliest times; and at a moment when Medical Reform is so much talked of, a historical sketch of this sort will be found both interesting and instructive by our readers.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

DECEMBER 4TH, 1851.

DR. FLETCHER IN THE CHAIR.

A very large Tumour of the Uterus, lying upon an enormous Tumour of the Right Ovary, formed in part of solid tissue like the Uterine Tumour, and chiefly of a large Cyst, containing thin Blood, the whole undergoing Cell Degeneration; numerous Minor Tumours approaching to fungus in character.—By GEORGE ELKINGTON, Esq.

Sectio-cadaveris.—The intestines were slightly glued together by recent peritonitis, and the abdomen contained a considerable quantity of opaque white fluid, not unlike thin pus. A large tumour, having the external appearance of the uterus, immensely hypertrophied, occupied the lower part of the abdomen. On raising this, which was easily done, it was found resting upon another softer tumour, which occupied all the posterior part of the abdomen, resting upon the spine, the pillars of the diaphragm, and lumbar muscles, and extending into the pelvis. In endeavouring to remove the first-mentioned tumour by an incision through the vagina, the knife passed through the

bladder, which perhaps was somewhat distended, and through the vagina, and opened some part of the last mentioned tumour lying behind the vagina; from this flowed a very large quantity of fluid, deeply coloured with dark blood, to the extent, certainly, of *two quarts*. Mr. Elkington thought three, at least. In this fluid were contained fragments of tissue, looking more like lumps of fibrin, which, however, they were proved not to be. By this drain the posterior tumour was materially lessened, though still forming a large mass. The whole mass was taken out altogether, and was removed for inspection; it did not adhere to the surrounding parts. All the other organs of the body were quite healthy. The tumour in front proved to be a single very large tumour, developed in the wall of the uterus on the left side; it was entirely enclosed by a thick prolongation of the uterine wall; it lay entirely on the left of the uterine cavity, was greatly elongated, was curved round its right side, although externally there was no indication of the situation of the cavity. The os was open and natural. The mucous membrane of the uterus was deficient in the upper part for about the space of a half-crown, exposing the tumour. From the left side of this larger tumour, at the upper part, projected another tumour, about the size of an egg, attached by a broad pedicle. The left ovary lay on the upper part of the tumour. The other large tumour was connected with the right side of the uterus by the broad ligament. It was plainly the right ovary which had twisted itself back, and had developed itself behind the uterus. The Fallopian tube lay at the upper part, dilated to the calibre of a goose quill, until it approached the uterus, when it was greatly contracted, and I think was not pervious to the organ. The large ovarian tumour consisted of a very large sac, still containing a quantity of thin dark blood, in which lay small masses of debris. The upper part of the wall was very thick, and formed a mass of tumour nearly resembling the one connected with the uterus. The posterior wall was also thick, but very irregularly nodulated by small tumours, which had more of a fungoid aspect. The structure of the uterine tumour seemed to have been of lobules of various sizes, connected closely together, of a smooth, yellowish, homogeneous tissue. The whole tumour much resembled in its characters the description given by Sir A. Cooper of the chronic mammary tumour; the centre, however, was very friable, and readily broken up; it seemed in process of assuming a fungoid character. The small tumour, springing from it, was much softer and more vascular, and turned out of its capsule like a kidney; it contained extravasations of dark blood, and altogether presented a great admixture of a fungoid character in its structure. The tumour, which formed the upper wall of the large cyst, had evidently been much diminished from below, apparently by a process of degeneration; its general aspect was like that of the uterine tumour, but it was softer, more vascular, and contained streaks of extravasations, and, besides, small cavities filled with coagulated blood. The posterior wall presented tumours, many entirely fungoid in their character.

Microscopic Examination by Dr. Russell.—The exterior of the tumour in the wall of the uterus was of a distinctly fibrous texture; it was firmer than any other part; the fibres seemed rather broad, in some respects resembling involuntary muscular fibres, though the tumour was perfectly distinct from the portion of uterine tissue prolonged over it. It did not present any fat. The remains of the ovarian tumour constituting the upper and very thick part of the wall of the cyst, consisted of fibrous tissue also, much as the uterine tumour; a large portion of it presented flat bands, but a large part also a more delicate fibrillation, but nowhere marked as in genuine fibrous tissue; it was in part in broad strands without definite arrangement, in part in large sheets. Portions of the tissue of the ovarian tumour were scattered over with small oil globules, generally gathered into small groups (indicating, I suspect, a stage towards formation of cells), in places, however, strewed over the specimens. In some specimens there were bodies strewed over the surface having just the character of nuclei of cells. By acetic acid the tissue of the ovarian tumour became more transparent, retaining, however, its fibrous markings, which in parts became more distinct, and the oil globules were thrown up more prominently. In the water around many specimens there floated the cells to be hereafter mentioned, indicating the formation of these cells in the heart of the fibrous tumour. The centre of the uterine tumour was very friable and crumbling, and consisted entirely of cells; they floated abundantly in the water employed, and seemed, by adhering to one another, to form the solid portion. Most of them were variously caudate, and resembled epithelium more than other cells. Their wall was very delicate; in many the nucleus very distinct, in other fainter and more delicate.

It appears that these were fibrous tumours, broken down by degenerating into cells; this process had gone on extensively in the ovarian tumour, and had nearly destroyed it; it was proceeding in the uterine tumour in the centre. The fragments washed out of the large cyst were plainly debris of the tumour. The process of transformation into cells appears to have gone on throughout a great part of the tumour at once, more vigorously towards the centre, but not confined there, and extending thence, for cells were formed in the very heart of the tumour.

The subject of this tumour was Mrs. Jennens, aged 46, the mother of two children of the respective ages of 25 and 23. Her first labour was rather tedious, and the second very quick, the child being expelled without much previous pain, while she was in the act of cleaning a fender. She walked up to bed, and went on well until the end of the fifth or sixth day, when she was seized with inflammation of the bowels, and was confined to her room for eight weeks. She remained in a very delicate state of health for some time subsequently, and was informed by her medical attendant that she would never again become pregnant. She first became aware of the existence of a tumour about two years after her last confinement; it then lay

rather to the right side of the pelvic region, and was about the size of a hen's egg. It afforded her very little inconvenience, and appeared to increase almost imperceptibly until about two years ago, when the catamenia ceased. After this period the tumour increased more rapidly, and became the seat of frequent pain and uneasiness.

I first saw Mrs. Jennens in March, 1850; the tumour was then about the size of a small foetal head; it occupied the pelvic region, and appeared to be firmly impacted in the cavity of the pelvis, feeling like the uterus when firmly contracted after parturition. The tumour was very tender to the touch. She had a quick pulse, sickness, and vomiting, and appeared to be suffering from inflammation in the tumour and peritoneal covering. These symptoms were removed by leeches, fomentations, &c., and in a short time she was restored to her ordinary health.

In September, 1850, I was again requested to attend her. The tumour had undergone considerable increase in size, and she was again suffering from local inflammation, which was removed by similar means as before. In December, 1850 she again became worse, and suffered from great pain in the left iliac region, in which direction the tumour appeared to be rapidly extending. There appeared to be a distinct tumour on the left side, about the size of an orange, which seemed to grow from the side of the original swelling. This increased rapidly during the months of January and February, 1851, and the morbid mass also extended itself into the right iliac region, and ascended higher into the cavity of the abdomen. About this period she suffered from retention of urine, and for some weeks it became necessary to pass the catheter several times daily. These symptoms gradually subsided as the tumour rose in the abdominal cavity, and she again became tolerably comfortable. The tumour, however, steadily increased, and assumed a nodulated character; several smaller ones arising from its upper part; the development of each being attended with symptoms of local inflammatory action. At the end of March her sufferings became much increased. The tumour grew rapidly in all directions, and she had almost constant pain and vomiting, which, with occasional periods of amelioration, continued to grow worse until the period of her death, which took place on the 20th November, 1851.

Transverse Fracture of the Patella.—By MR. MOORE.

This specimen was obtained from an old man who had the misfortune to fracture his patella some time back. The specimen has been removed from the body some days; and five weeks and three days elapsed from the date of the accident, up to the time of his death, which took place in consequence of debility and bed-sores. The two portions of the bone are seen firmly united by ligamentous structure, which has not yet acquired the characteristic colour, being still dark and containing blood. The parts round the joint, integuments, &c., were all exceedingly vascular. The ligament is very short, and, considering the restlessness

of the patient, he having at times become much excited, trying to get out of bed, &c., the separation between the fragments is very little indeed.

Dilatation of the Aorta.—By MR. MOORE.

The subject from which this specimen was obtained died generally anasarcaous. She had suffered from cedema pedum for some years, and had frequently had attacks of bronchitis. During life a loud bruit was heard in the course of the aorta. The valves of the heart were all healthy, but the heart itself was somewhat, although not considerably, hypertrophied. There are numerous hard deposits in the tissue of the vessel, which is nearly thrice the size of the normal state.

Fatty Tumour.—By MR. MOORE.

This specimen was removed from the neck of a patient near sixty years of age. It had been growing some twenty years, and of late had caused headache and giddiness by its pressure on the vessels. It was situated beneath the platysma myoides, and hung over the clavicle, almost reaching the mammae. Its size when removed, was larger than it now seems, and it weighed nearly three pounds. The operation was performed by Professor Sands Cox.

Necrosis of the Upper Jaw.—By MR. MOORE.

This portion of bone consists of the greater part of the alveolar process of the right side of the upper-jaw. It contains the two last molar teeth, and was removed from a patient who eight months back had an attack of small-pox. It appears that on convalescence from this attack, the lower teeth first became loose and dropped out, and afterwards the bone became affected and a portion of that was removed. On presenting himself at the Queen's Hospital, some three months since, most of the upper teeth were found loose, and the portion of bone now shown, also in process of separation. Its complete detachment, however, was not effected until some days back. The patient is now well, with the loss of the teeth. It is remarkable there was never any affection of the soft parts. It could not be ascertained whether mercury had been taken.

Necrosed Bone discharged from the Nose.—By MR. MOORE.

These portions of bone passed from the nose of a patient affected with secondary syphilis, who was under the care of Professor Parker. There are four pieces of bone, one of large size, being nearly half an inch square, and four lines in thickness. The other portions are smaller. They probably came from the sphenoidal cells, but this cannot be stated with certainty. There was no visible deformity of the nose caused by their coming away.

Diseased Humerus.—By MR. MOORE.

The patient from which this specimen was obtained, met with an accident eight months before his admission into the hospital, and fractured the lower-third of the

humerus. He applied to some empiric who put the arm straight and kept it so for some time, the result of the treatment being the state found on admission. The forearm and hand were very œdematous, and the elbow joint ankylosed. There was a wound at the seat of fracture, through which the probe detected dead bone. There had been no union, and a false joint existed, allowing of some degree of motion. There was also another external wound near the surgical neck, where likewise dead bone was found. The boy was of a scrofulous aspect. Amputation was performed by Professor Knowles, and the patient discharged in a short time well. The specimen shows a sequestrum contained in a bony canal at the lower-third of the humerus, and also another near the upper extremity, with a cloaca in the outside shell at the latter point.

STOCKPORT MEDICAL SOCIETY.

At the monthly meeting of the Stockport Medical Society, on the 7th of April inst., George Downes, Esq., President, in the chair, the Medical Bill prepared by the Worcester Council of the Provincial Medical and Surgical Association was considered, and on the motion of J. Medd, Esq., seconded by John Rayner, Esq.,

It was unanimously resolved,—

“That the general principles of the Bill are worthy the earnest support of the profession, and the members here present pledge themselves to use their utmost exertions in furtherance of such general principles of the said bill becoming law.”

It was also resolved,—

“That the above resolution be forwarded for insertion in the *Provincial Medical and Surgical Journal*; and that when the Bill is brought before Parliament, a copy of it be sent to the county and borough Members, with a request that they will support the same.”

Foreign Department.

FRANCE.

ACADEMIE DES SCIENCES.

M. WALLER, of Bonn, laid before this Society a new method of studying the nervous system, which consists in making sections of its structure at different places, whether of the nerves or of the spinal marrow, and after keeping the animal alive for two or three months, to determine the changes which have taken place, by the aid of the microscope. He has thus instituted some important researches on the reproduction of nerves.

M. REYNOSO further illustrated his views on the *production of sugar in the urine*. It may be remembered (see *Prov. Journ.* January 7th, 1852,) that he considered the presence of this ingredient, intimately allied to disturbances of the respiratory function, his present object is to confirm the statement then made, which he

does by affirming that he has found sugar in the urine in phthisis, in pleurisy, and in chronic bronchitis and asthma. He has likewise found it in the urine of patients who were taking arsenic and the preparations of iron.

M. ROBIN presented a memoir in which he proposed some new views on the causes of albuminous urine. “In the state of health,” he observed, “the albuminous principles are oxygenized in the blood, and the resulting compounds—urea and uric acid, pass off by the kidneys. If, then, from any cause, the due combustion of albumen is interfered with, it passes through the kidneys unchanged, instead of in the form of urea and uric acid. This theory he considers to be supported by numerous facts. Thus, the urine becomes albuminous:—1. In croup, in aggravated cases of ascites, in phthisis, and in advanced pregnancy, all of which disturb respiration. 2. In cyanosis or diseases of the heart, which induce a state of semi-asphyxia. 3. In diseases or injuries of the nervous centres which are marked by a fall of animal temperature. 4. In that state of exhausted nervous energy, to which the name of *courvature* is applied. Some confirmatory facts are also, he considers, to be derived from comparative anatomy. Thus, in general, he states, the urine of birds and mammals does not contain albumen. Among reptiles, on the contrary, which are distinguished by a low animal temperature, albumen is always present in the urine.

M.M. DESGRANGES and DEWAY, of Lyons, reported a successful case of transfusion of blood. The patient was a female aged 27 years, whose life was placed in the greatest jeopardy by uterine hæmorrhage. All other measures failing, the operation of transfusion was performed. The immediate effects were satisfactory, but in a few hours there was great excitement with delirium, the patient at length becoming so violent as to require restraint. These uncomfortable symptoms, however, gradually subsided, and in a few days the patient was able to be taken from her bed without fainting. She had subsequently an attack of phlegmasia dolens, but eventually quitted the hospital well.

A report was read on a memoir by M. LEREBoullet “On the *Intimate Structure of the Liver*, and on *Fatty Degeneration of the same Organ*,” The opinions of the author on each section of his inquiry are expressed in the following propositions:—

Healthy Structure.—1. The bile is secreted by the hepatic cells. 2. The livers of molluscs and crustaceans contain two sorts of cells, biliary and fatty; both of which multiply by endogenous generation. 3. The liver of vertebrate animals is composed of lobules of various dimensions. These lobules or granulations are most distinct in the liver of the pig, as they are surrounded by a continuation of Glisson’s capsule. In man the granulations are often confused. 4. The true colour of the liver does not depend upon the bile, but upon the relative repletion of the portal and hepatic

veins. When the former are gorged, the circumference of each lobule is darker than the centre, and *vice versa*. 5. Each lobule may be considered as an epitome of the liver itself. 6. The secretory cells of the liver are veritable follicles, as is seen more distinctly in the fatty state of the organ, the fat being contained within their cavities. 7. These cells contain nuclei and nucleoli, grey or yellow granules and fat globules; one or more of them may, however, be absent. 8. In the foetal liver of mammalia there are two sorts of cells—fat cells, and endogenous bile cells, the preponderance of the former tends to the supposition that they are a prior state of the latter, and that the bile cell is the perfect condition. 9. The secretion of bile is not produced from a portion of a lobule only, but takes place throughout its whole extent. 10. All the lobules have their axis traversed by a venule, several of which either unite to enter an hepatic vein by a single trunk, or do so separately. 11. The extra-lobular biliary canals, arise from the surface of the lobule, and after forming larger trunks, take their course in the intercellular tissue called Glisson's capsule. 12. The ramifications of the vena porta surround each lobule. 13. The hepatic artery does not ramify over each lobule, but sends its capillaries to the coats of the other vessels, and especially to the fibrous capsule of the liver. The capillaries of the artery and portal veins do nevertheless insinuate as infection passes from one to the other. 14. The blood of the hepatic artery does not seem to contribute to the secretion of bile, or at best plays but a secondary part in that function.

Fatty degeneration of the liver, according to the author, consists in an accumulation of fat globules in the interior of the cells or follicles of the lobules, and not the spaces between the lobules. When cells are thus altered they cease to secrete bile, and the lobules gradually acquire a pale fawn colour. The reason of this the author states to be that the engorged cells press upon the portal capillaries, and prevent the ingress of blood. The author has studied the process of forming diseased livers of geese, and determines that in many respects it differs from true fatty liver of spontaneous disease. The intimate cause of the change is stated to be imperfect oxygenation, and it is therefore most commonly seen in diseases which interfere with respiration.

On Neuralgic Amaurosis.

M. Tavnigot gives this name to the complete or incomplete, partial or general, paralysis of the nervous retina under the influence of neuralgia of the fifth pair of nerves.

"The mode of action exercised on the eye by the fifth pair of nerves affected with neuralgia, is," states M. Tavnigot, "subject to certain laws which I will endeavour to describe. I admit two species of neuralgic amaurosis, very characteristically distinct from each other. The one is attributable to a neuralgic condition of the extra-orbital branches of the trifacial nerve,—this is

the extra-orbital neuralgic amaurosis; the other arises from a neuralgic condition of the ciliary nerves,—this is the intra-orbital neuralgic amaurosis.

"The extra-orbital neuralgia of the fifth pair appears to me to act on the retina, producing a paralysis of that membrane. This paralysis results from a want of equilibrium in the distribution of the nervous influence, as if the excessive waste of this fluid by the extra-orbital branches took place at the expense of the ciliary nerves, which would thus be more or less deprived of it.

"Both one and the other form of neuralgic amaurosis appear to have an analogous origin, although differing completely in their symptoms. The cause of neuralgic amaurosis, considered in a general manner, is an abnormal state of the blood, resulting from an irregular assimilation, or a vicious re-assimilation.

"Local treatment is not likely to be successful, unless combined with general treatment."

General Retrospect.

ANATOMY AND PHYSIOLOGY.

On the Function of the Liver.—By Dr. G. WYLD.

Dr. Wyld is the author of a paper written with the object of disproving the doctrine generally entertained that the liver is simply a depurating or excrementitious organ, *vicarious* in its action with the lungs; and to propound the theory that it is a *secreting* organ, *antagonistic* with the lungs, and tending to reconstruct the tissues, as the action of the latter is to destroy them. This view he supports by a train of ingenious reasoning, which we cannot afford space to reproduce; the summary of his views may, however, be thus expressed:—

1. The main object of the liver is not to excrete hydro-carbonaceous matters, the result of waste of tissues; and therefore its function is not vicarious with respiration.

2. The grand function of the liver is to secrete bile, without which nutrition is impossible.

3. The grand office of bile is to create oil globules and fat molecules, as they are found in the chyle.

4. The oil is different from ordinary oils, and is more nutritious.

5. In proportion to the relative size of the liver will be found the activity of the formative processes in animals.

6. The liver has the power of decomposing water, and using the hydrogen thus set free for the creation of bile.

7. That as the lungs may be called *oxygenators*, so the liver may be called the *hydrogenator* in animals.—*Monthly Journal of Medical Science*, March, 1852.

PRACTICAL MEDICINE AND PATHOLOGY.

Treatment of Accidents from Chloroform.

In cases of accidents from chloroform Dr. Snow considers that the best means of preventing death is

artificial respiration. From experiments which he has made on animals, he considers that, if it were performed within half a minute after the apparent death of the patient, it would in most cases be successful. He thinks that the most safe and prompt method of performing it, in the human subject, would be to apply the mouth to the nostrils of the patient, and draw as much air as possible from the lungs, allowing them to be filled again by the elasticity of the ribs and atmospheric pressure. If this measure should not quickly succeed, he would recommend that the external jugular vein should be opened while the artificial respiration was still continued; for he has observed, in his experiments, that the right cavities of the heart became distended when its action failed, and that opening a vein near the heart improved the force and extent of any contractions which still continued. He has tried electricity on animals without success.—*Medical Times*, March 6th.

Test for the Purity of Cod-liver Oil.

Sir James Murray, in calling attention to the numerous adulterations which are made by druggists, incidentally speaks of cod-liver oil, which is extensively falsified by the admixture of other oils, animal and vegetable. The test which he recommends was suggested to him by the knowledge that in a cotton factory the spindles which were made of brass always obtained a deposit of verdigris when a bad oil was used, which was not the case with pure spermaceti oil. The test consists in heating the suspected oil in a copper capsule; if it be genuine cod-liver oil, no discolouration occurs, whereas the spurious oils throw up a quantity of the salts of copper, forming a green film on the surface.—*Dublin Medical Press*, March 24, 1852.

SURGERY.

Operation for Intestinal Obstruction.

Several cases have been recently read before the Medico-Chirurgical Society, in which the operation of opening the colon has been performed, for insurmountable intestinal obstruction. The first is related by Mr. Adams, of the London Hospital:—The patient was a lady, aged 35, who was supposed to be the subject of cancer of the rectum. After the usual attempts to relieve an insurmountable constipation, enterotomy was performed according to Mr. Luke's method, with complete relief. Since the operation, her health has been better than she has known it for years. A light truss is used to obviate the annoyances of artificial anus.

A second case is related by Mr. Clement, of Shrewsbury. The patient was a female, aged 47, the subject of obstruction of fourteen days duration, with all the symptoms of ileus; pulse small and fluttering. On the 10th of October, 1841, as the patient's state appeared hopeless, unless relief could be obtained by operation, the patient was placed on her abdomen, and the colon, which was felt to be distended, was opened in the right lumbar region. A large quantity of fluid fæces escaped, with immediate relief; and at the end of six weeks the patient was able to walk out of doors. The patient lived more than three years with the artificial anus, and died of gradual exhaustion.

The structure, which was of cartilaginous hardness, was situated in the transverse colon.

A third case, by the same author, occurred in the person of a muscular man, aged 43, who had stricture of the rectum, about six inches from the anus. After gradually increasing constipation, the bowels at length became totally obstructed, and other means failing, an operation as in the previous case was performed on the 20th of June. At first no fæces escaped, nor was there any abatement of the hiccup and vomiting; however, in about eight hours an immense discharge of fæcal matter occurred, with some abatement of the symptoms. The state of the patient during the next seven days is detailed minutely; and it is stated that at the end of that time his improvement was very decided, and continued for ten days, when he was seized with rigors, followed by enlargement of the inguinal glands, and sloughing of the skin on the sacrum and in the groins. Death took place in July.

Mr. Baker, of Birmingham, likewise furnished a case in which the descending colon was successfully opened in the left lumbar region, for obstruction arising from disease of the rectum. The operation was performed on the 23rd of January, 1850, and the patient has since remained free from constipation, although symptoms are present which indicate the extension of the original disease.

At a subsequent meeting of the society, Mr. Cæsar Hawkins read notes of a successful case of opening the colon, followed by an interesting analysis of forty-four cases of artificial anus. These cases were divided into those which had been operated on through the peritoneum, seventeen in number, and those in which the bowels had been opened external to that membrane, twenty-seven in number. The nature of the operation was also described, as well as the character of the obstruction, and the result, with the cause of death in the fatal cases. It appears that ten had died within forty-eight hours after the operation, and twenty-one within five weeks; and that twenty-two only could be said to have recovered from the operation; of these also it appeared that six died within six months, and only nine were known to be alive at the end of one year. Sex did not seem to influence the success of the operation. The tables showed, in reference to the cause of the obstruction, that in seventeen it was of cancerous origin. The tables of the situation in which the artificial anus was made, led to remarks on the comparative value of Littre's and Callisen's operation, from which it appeared right to operate external to the peritoneum on the right side; but the question was left undecided as to the descending colon.—*Lancet*, March 6.

MIDWIFERY.

Case of Spontaneous Evolution.—By S. BRAND, Esq.,

The following is reported as an instance of spontaneous evolution:—

On the afternoon of Friday, the 9th of January, Mr. Brand was called to Mrs. P., who had just been brought home on account of the membranes suddenly rupturing, with escape of the liquor amnii. He found the pains were but slight, the os uteri had not begun to dilate, and there was no indication of the presentation.

On Sunday morning the 11th, true labour pains commenced; the elbow presented; but on account of the firm contraction of the os round the upper part of the arm and wrist, the author was not able to get his finger through to reach the parts above, and from its swollen condition, to learn with certainty whether it was the elbow or knee. On examining the uterus through the abdominal parietes, he found it firmly contracted, remarkably small and low in the pelvis; the pains at this time were not very active, and the discharge of water had entirely ceased. After a time, the hand, with the palm to the sacrum, slipped into the vagina. Having no longer the slightest doubt he determined on turning, if possible, but was not able to get so much as the tip of one finger into the uterine cavity, and the attempt was attended with great suffering to the patient. Immediately on the release of the child's hand from the os, the expulsive efforts became exceedingly powerful, and followed each other almost without intermission; and finding that with each the arm was descending, the author did not feel justified in using more force, but made up his mind, for the present at least, not to interfere. Gradually the whole arm was protruded, and the point of the shoulder passed under the arch of the pubes, and never receded; the side of the chest now came upon and separated the labia, and the perinæum was fearfully distended. The patient's age (twenty,) being in her favour, notwithstanding this was her first labour, the author was able, by steady support, to save this structure from laceration. A delay of about ten minutes took place before the breach was expelled. He then obtained a purchase in the fold of the thigh, and assisted the delivery of the legs; this being accomplished, there was a cessation of the pains for two or three minutes; they then returned; and having first brought down the left hand, he delivered the head (face to the sacrum) in the usual way, without difficulty.

The child (male) was born dead; it measured nineteen inches, well developed, and of average bulk. The woman has recovered without a bad symptom.—*Lancet*, March 13th.

On the Connection of Menorrhagia and Gastro-Hepatic Disturbance.—By Dr. MACKENZIE.

In allusion to this subject, the author of a very valuable essay, "On the Relations of Uterine to Constitutional Disorder," writes somewhat to the following effect:—

Many writers have remarked that in most cases of excessive menstruation the general health is greatly deranged. The cases recorded tend to show that in a certain proportion, at least, the symptoms of gastric derangement, when met with in connection with hæmorrhagia, are its antecedents rather than its consequences; and inasmuch as the cure of uterine disorder is often to be effected by that of the chylo-poietic, without any specific treatment whatever, it must follow that it is not merely its antecedent, but its positive cause also. Further, many collateral circumstances are in favour of this view. It was observed by Mr. Abernethy. Thus his observations in surgical cases led him to attribute many hæmorrhages to a sympathetic affection of the heart and arteries, excited by disorder

of the digestive system. The connection between uterine hæmorrhages and disorder of the stomach and digestive organs has also been specially referred to by Dr. Ayre, in his work on disorder of the liver. He has drawn attention to the fact that many forms of *post partem* hæmorrhage depend upon it. He ascertained that in many of these cases the liver was specially affected, and that calomel was the most efficient remedy. At first he ascribed its efficacy in restraining uterine hæmorrhage to the evacuation of morbid matters from the bowels; but further experience convinced him that the efficacy of the medicine was due to its alterative action upon the digestive organs and liver.

So also Sir James Eyre's cases, in which oxide of silver is exhibited as a remedial agent in uterine hæmorrhage, would seem to bear a similar interpretation; for he has shewn that this medicine, which has extraordinary power in allaying the irritability of the gastro-intestinal mucous membrane, and as such is deservedly popular in dyspeptic affection, is at the same time a valuable remedy in cases of menorrhagia. The efficacy of bismuth in similar affections is in favour of the same doctrine; and indeed it may be conclusively shewn that many forms of menorrhagia owe their origin chiefly to an irritable or disturbed state of the stomach and digestive organs, and that where these pathological conditions coexist, we are not justified in assuming that the latter are the mere consequences of the former. On the other hand, the history of such cases will often demonstrate that it had preceded rather than followed upon it.—*London Journal of Medicine*, March.

Two Cases in which an Ovule, or its remains, were discovered in the Fallopian Tube, after Death during Menstruation.—By Dr. LETHEBY.

At the commencement of the paper the author points out that the arguments which have been adduced in support of the opinion, that the menstruation of the human female corresponds to the "heat" or "rut" of the lower mammalia, and that an ovum is normally matured and thrown off at each menstruation, are entirely of an analogical character; and that, although the ovaries of women who have died during the menstrual period have been frequently examined, and Graafian follicles found in a recently-ruptured state, yet the discovery of the liberated ovule had not, so far as he was aware, ever been detected. The importance of his cases rests upon three grounds—namely, 1st, the circumstances under which the women had died, which forbade the idea of recent sexual intercourse; 2nd, the finding of recently-ruptured Graafian follicles; and, thirdly, the discovery of the ovule and its remains in the fluid matter of the fallopian tubes.

In the first of the cases recorded, the woman died during a menstrual period. She had been an inmate of the London Hospital for twenty-four days before her death, where she was closely watched day and night by a nurse, in consequence of her having attempted self-destruction, by cutting her throat, twenty-nine days before her death.

An examination of the body showed that the pelvic viscera were much congested, that the uterus was considerably enlarged, that the vagina contained a sero-

sanguineous fluid, and that the hymen was unruptured. The ovaries were covered with stellate fissures or cicatrices, and at one part of the left organ there was a purple spot, having a ragged hole in its centre. By means of an incision into the gland through this spot, it was found that the opening led into a small cavity, which was surrounded at its lower part by a dense tissue, infiltrated with dark coagulated blood. After macerating in spirit for a short time, it was noticed that the clot consisted of four parts, which the author describes.

In other parts of the ovary several false *corpora lutea*, in different stages of decline, were found. The fallopian tubes were highly congested, and the cavities of the tubes were filled with bloody mucus. In the left, at about an inch from the fimbriated end, was a small vesicular body, which Dr. Letheby considers was an ovule, for it consisted of nucleated cells and oil globules.

The second case was that of a girl who had died at St. Luke's, where the patient had also been closely watched. In this case the right fallopian tube contained a body resembling an ovule, which under the microscope was found to consist of nucleated cells, of a transparent ring, enclosing an opaque granular mass, and a highly pellucid spot. The *corpora lutea* were composed of granular corpuscles and oil globules. The author's conclusions from these cases are:—

1. That ovules escape from the ovaries of women during the period of menstruation, and that their escape is quite independent of sexual congress.
2. That the mere presence of a *corpus luteum* is not a proof of impregnation.—*Proceedings of the Royal Society.*

Correspondence.

MEDICAL BENEVOLENT FUND.

To the Editor of the *Provincial Medical and Surgical Journal.*

MR. EDITOR,—Pardon me for asking the attention of your readers at this time, to the Medical Benevolent Fund. At a period when such great efforts are making in favour of *quasi-benevolent* projects, all having a root of selfishness in them, and therefore essentially partaking of the *provident* character, it is really necessary to bring the claim for support of the Benevolent Fund prominently before the profession, because having nothing to recommend it to notice but its own *pure, unselfish, charitable* character, it is necessary that its holy principles should be constantly brought home to the heart of every individual concerned in its success. And what individual in the profession is not concerned in its success? What individual is there who, in prosperity, can refuse to listen to the plaints of the wretched, or can turn a deaf ear to the silent voice of untold misery;—or who, in adversity, can refuse to lend a helping hand to those still more unfortunate than himself—to those who are ready to perish?

The Committee of the Benevolent Fund have wisely determined to hold a public festival on behalf of this fund, on the 20th of May, when the Earl of Carlisle has consented to preside. Their object in this movement is to extend the knowledge of their Institution, to let its claims to support be better known, and to augment its funds. I am well pleased to notice a goodly list of stewards upon that occasion. But there are those whose professional duties have precluded their accepting the office of steward;—there are those whose distance from London has offered an insuperable barrier;—there are those whose own slender means have prevented their *purchasing a ticket*, in addition to the necessary expenses of travelling, and passing a night in London;—there are those whose state of health forbids the excitement of a public dinner. But to each of these individuals let me put the question,—What have *you* done to relieve the necessities of your starving brethren or their families? What have *you* done to relieve the mental agonies of him who finds himself incapacitated by paralysis from the active duties of life; or to soothe the sorrows of the widow and orphan, deprived by sudden sickness or accident of their only support? What have you done in support of that helpless idiot orphan, who once enjoyed all the luxuries of life, but is now left to the *charity*—shall I say, the *neglect*, of the great professional family? What have you done towards the education of those orphans who have been left without any means of support? What have you done towards the comfort of that literary lady, who is struggling to earn her precarious bread by the most ill-paid services?—or towards those who are equally contending with the evils of penury by the help of their own fingers—stitch, stitch, stitch—till, with aching head and almost sightless eyes, the temporary forgetfulness of sorrow is sought for in that “Tired Nature’s sweet restorer—balmy sleep,” to awaken after a brief period of oblivion, to the aggravated consciousness of unpaid labour?—or what have you done in favour of the countless forms of wretchedness, which exist festering, though concealed in the great walk of professional life? Tell me not that you are a subscriber towards this or that *provident* local fund; then let me ask what have you done to relieve that helpless family, upon whom you have turned your back and coldly told them there is no hope for them, because their circumstances in life had forbidden their becoming members of your *provident* society? Tell me not that you have subscribed towards the British Medical Fund, or the Medical Benevolent College—excellent institutions in their way—but let me ask you, what have you done for those who have not had it in their power to secure the benefits of the *one*, or who cannot exist, till the *other*, yet *in posse* be actually in being and dispensing its benefits—and even then living unrelieved in the vain hope of raising which it can never reach:—and which *can be never reached* except by a purely charitable fund—by an institution which stretches out its hand to relieve temporary distress by temporary aid: the Medical Benevolent Fund, the *only* institution in the kingdom which can expend the funds with which it is intrusted in relieving the wants of our brethren;—the only Institution which gives, hoping for nothing again;—which in the hour of sorrow steps in with its soothing

sympathy;—which listens to the voice of *real distress* and promptly relieves;—which reinstates the pecuniary beggar to his lost position in society, and which restores to him the means of again providing for his family; and which enables the *widow* to support her helpless orphans.

Allow me, therefore, Mr. Editor, to press the claims of this Institution upon the notice of your readers, and to ask each individually if he has done what he could in support of this purely Christian fund.

I have no jealousy towards the local provident funds,—I have no jealousy towards the British Medical Fund,—I have no jealousy towards the Medical Benevolent College: I envy them not their successes—I support them all; but I must say that no one, nor all combined, can ever supply the place of the Medical Benevolent Fund.

It has been asserted by a correspondent in your last journal, that we ignore the existence of the local funds; but this is a mistake, we have known and acknowledged their value to a far greater extent than Dr. Souby, who appears not to be aware of the existence of several. But we have always contended, and we still assert, that these funds *relieve their members only*,—that *their members are entitled to relief*,—that as such they are truly *provident* funds, and *not benevolent*, except in the limited sense attached to all other mutual insurance societies.

It is often suggested to me, that it is a pity there should be so many funds with *ALLIED* objects, and that it would be better to have *one comprehensive fund, and combine all the objects by one machinery*. But, as I have already stated, all the funds combined cannot supply the place of the Medical Benevolent Fund; and there can be *no amalgamation*, because the *principle* upon which we proceed is dissimilar. Ours is *truly charitable*, all others are *partly provident*. It is quite true, that if the other funds choose to make over their resources to our fund, we could dispense them; and as the far older and long-tried society, we have a claim which more modern institutions have not. But this project they will never adopt, and it is obvious that we dare not give up our funds and our principle at the same time, and hand over to others the distribution of the means which have been intrusted to us. It has been suggested to me, that all these objects might be *combined*, though *not amalgamated*, and that by a *compulsory* payment from every individual employed in the profession. I will not say what I think of such a *compulsory provision, except that it is not charity*, and to ask "*Who will bell the cat?*"

And now, Mr. Editor, let me seriously inquire of each one of your readers,—Have you yet cast in your mite to the treasury of the Benevolent Fund? Have you done what you could to relieve professional distress; or have you been determined to ignore its existence, except in a shape in which it may be provided against? Have you listened to that feeble cry of the helpless orphan, or have you determined to pass it by, with a cold reference to the fact, that the father might have provided for the day of distress and destitution? Have you left it to the rich and prosperous (*the few*) to make up for that which can only be thoroughly accomplished by the combination of the many? Have you forgotten the aged widows, who now depend upon our fund for their only sustenance: or have you "*remem-*

bered to forget" their wants; and because you do not see those wants, have you persuaded yourself that there are none such in existence?

And Mr. Editor, let me most earnestly entreat your readers' attention to the facts of the case, and let them not listen to the arts of evading a charitable subscription; let them not be as the priest and the Levite which passed by on the other side; but let them emulate the good Samaritan, who proved himself to be the neighbour of the wretched and the miserable, by relieving their distress;—let me earnestly beseech them to listen to the voice of conscience, and to that still small word of affectionate interest which proceeds from the heart;—let them in this instance listen to their *feelings*, and what the heart prompts let the hand execute directly;—and then may the tired head rest upon its pillow at night with the soothing reflection of having done what it could for others as well as for himself, and of having executed one grand Christian duty, for the "*greatest of these is charity*."

I remain, Mr. Editor, yours faithfully,
W. NEWNHAM, Treasurer.

P.S. There are a few persons in arrear with their subscriptions. I trust the present appeal will remind them of their debt, and of the necessity for *payment*.

THE PHARMACY BILL.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I am anxious to call the attention of the provincial general practitioners to the "*Pharmacy Bill*" of Mr. Jacob Bell, which has been silently but surely passing through the House of Commons. It has hitherto met with little or no opposition, the *Medical Times* being the only journal which has made any stand against it. I think the *Lancet* and your journal* have each noticed it with a rather laudatory leading article, which I regretted to see, because I feel assured that without considerable modifications and safeguards to prevent chemists and druggists from acting as medical practitioners, the Pharmacy Bill will prove highly injurious to the public and to surgeons in general practice. I have just addressed a letter to the editor of the *Lancet* on the subject, which, as containing my sentiments more at length, you will much oblige me by inserting in the next number of your journal.

I would only further remark that there is no time to lose. Evidence is about to be given against the bill in its present state before the Select Committee, but should the necessary alterations not be made, I would recommend that the measure be *opposed in toto*. This might be effectually done by even a single practitioner in every parliamentary district signing a petition against the measure and entrusting it to his own member for presentation.

In the meantime I beg the serious attention of all general practitioners to the bill, and to its probable effects on their prospects. I can quite understand why

* This is a mistake, no such article having appeared in this journal.—
ED. JOURNAL.

the Colleges, who have so frequently neglected or opposed the interests of the general practitioner, are *supporting* the bill! The suicidal conduct of the Society of Apothecaries, who I understand are not opposing the measure, and are thus betraying the interests of their Licentiates, I confess I do not comprehend.

I am, Sir, in haste, yours faithfully,
GEORGE WEBSTER.

April 21, 1852.

To the Editor of the Lancet.

SIR,—I am much surprised at the apathy which seems to pervade the ranks of the general practitioners, both in London and the provincial towns, respecting the "Pharmacy Bill." That measure has been read a *second time* in the House of Commons, and is now in Committee, and if not strenuously opposed, has every prospect of passing both Houses of Parliament, and becoming the law of the land. You, Sir, are a member of the Select Committee now sitting on the Bill, and I cannot help thinking that you are either deceived as to its probable effects, or that you are not as usual sensitively alive to the interests of the public and of surgeons in general practice.

I am strongly of opinion that should the Pharmacy Bill pass into a law, it will most injuriously affect the public, and seriously interfere with the legal practitioners of medicine. No man knows better than you do the frightful extent to which chemists assume the functions of medical men, and the fearful consequences which result from "counter practice," and even domiciliary visits. The present bill gives full power to the Pharmaceutical Society (already incorporated under a Royal Charter) to regulate with all the machinery of a Royal College the affairs and government of the chemists and druggists of England and Wales; and not contented with this, they wish to assume the same power over the chemists of Scotland. They contend not only for registration, and full power to make such bye-laws as they may think proper, without any control, but also for the sole regulation of the education and examination of all their future members.

And what is to be the course of their examination? Why—in the classics, in dispensing and prescriptions, in botany, in chemistry, in materia medica, in pharmacy, and in toxicology, which last word may include almost anything pertaining to the practice of medicine. I am rather surprised indeed that midwifery was not also included, which some chemists now boldly assume the right of practising.

Now, Sir, I ask my medical brethren, and I ask you, whether, with these considerable fragments of a medical education, the future race of chemists will not, on the strength of their examinations, and a showy diploma placed in their windows, most egregiously deceive themselves as to their amount of medical knowledge, and also sadly deceive the public into a belief that they are perfectly qualified to treat and cure diseases? My firm conviction is, that by the passing of the Pharmacy Bill, "counter practice" and the treatment of diseases by chemists, which now obtain to such an extent, will be increased at least *ten-fold*; and I look upon the measure as being fraught with great danger to the

public, and with great injury to medical men. Even the present race of chemists will, I presume, be entitled under the Act to another flaring diploma, and will consider themselves as better qualified by such a licence to pursue their present dangerous career.

I do not for a moment mean to charge the more respectable houses in London and in the larger towns with resorting to such dangerous practices; and I am convinced that Mr. Jacob Bell, and you, Sir, and others, may believe that this bill is calculated to prevent rather than promote the evils of which I complain. I regret that after much consideration of the subject I cannot entertain this view; and I know that many of my medical friends fully agree with me in the opinion which I have thus expressed.

It will naturally be asked what remedy I propose? Let me say at once that I would *not object* to the education of chemists under proper regulations. I *simply object to their assumption of functions for which they are not educated*. They may dispense the prescriptions of physicians and surgeons, and they may vend all the usual medicines *ad libitum*, except the strong poisons, such as arsenic (already guarded), prussic acid, oxalic acid, opium and its preparations, chloroform, &c., which ought to have been included in the arsenic bill. I would not prevent their doing anything which belongs legitimately to the trade or business of a chemist, but I would propose that a clause should be introduced into the bill, making it penal for a chemist to prescribe for, or treat diseases, or to act in any way as a legally qualified medical practitioner. I would restrict the chemists of this country as the pharmaciens of France and other parts of the Continent are restricted, and I would despise the maudlin nonsense respecting "the liberty of the subject in this free country," and would consider that as salutary and requisite which should evidently prevent the destruction of life or health. If Mr. Jacob Bell should object to such a clause, I would call on you, Sir, and on my medical brethren to oppose the Pharmacy Bill by every means within their reach.

There are other objections to the Bill, such as its inappropriateness pending a general measure of Medical Reform. I object also to the creation of a new Corporation with Parliamentary powers, when, in fact, the chemists ought to be joined to the Society of Apothecaries, whose present functions (which they are seriously neglecting if they assent to the Pharmacy Bill) must soon necessarily cease. But your space and my time are both exhausted.

I remain, Sir,

Yours faithfully,

GEO. WEBSTER, M.D.

Dulwich, April 21, 1852.

TREATMENT OF THE INSANE.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I have the honour of acknowledging and thanking you for the insertion of my letter of the 25th of February in your journal of the 17th inst., and

whilst I am preparing to conclude my reply to your correspondents, I beg leave to notice two passages in the second column of page 156, which are not quite correctly printed. The first is at the twelfth line, where the sentence—"I heard an instance where a young man was lately seized in his bed, at three o'clock on a November morning," which I inserted, because without proof the statement preceding it might appear to be incredible, ought to appear between short lines, or brackets. The other is at the bottom of the same column, and the mistake arises from my own erasures and omissions. The passage should run thus:—"The question, not of the private character, but of the official conduct of proprietors of asylums, and that of the merits of private asylums, however important, are both different questions."

I will take the same opportunity to notice the short letter of E. B. with no date, which has been forwarded to me, extracted, I believe, from your journal of the 31st ultimo. I never stated that E. B. had mentioned my name in his original communication, but in my letter of the 1st of November I replied to the *allusion* which he made to my name, when, after having attacked the report of the Alleged Lunatics' Friend Society, he observed, that no one could be astonished at the nature of the report, when they considered the wild or extravagant notions of the gentleman whose signature was attached to it, or words to that effect. E. B. would have acted more candidly, in either regretting his hasty allusion to my signature, or in defending the style of it. I, however, beg to assure him that I feel no offence at his allegations, because I know that many persons cannot believe that the system of confining alleged lunatic patients in private asylums without the knowledge of the grounds of their confinement, and without power to appeal to any tribunal for an inquiry into their case, or of communicating with their friends and legal advisers, and the cruel and ignorant treatment to which I was exposed and which I witnessed, and which I have had reported to me by others, is either true, or can deserve the strong language in which I have spoken of it. And they presume that the reforms which I advocate in this system, and which are founded, as I believe, on the soundest principles, must be as extravagant as that language appears to them to be from their unbelief of the truth of my statements, or from their want of reflection. With regard to my knowledge of insanity being slight or not, that is not the question between us. The objects which I and my friends have in view, are to prevent injustice, and cruelty, and outrageous violence being used to patients, under the pretence of care and cure and of the necessity of sometimes using force to subdue maniacal excitement. We do not pretend to interfere with the proper medical treatment of the insane; I believe, however, that on this point I might be able to throw out some hints that might be useful, or at least some very valuable cautions, particularly as regards the moral and spiritual effects which many medicines may produce, a subject which I have not yet seen treated on, and is well worthy of inquiry. My confinement, however, for two years in two different asylums, and the visits which I have paid to several asylums, both in this country and in France, have

given me some insight into the nature of this disorder. I will add, also, that in all other maladies the experience of patients is considered of some value by intelligent physicians, and my experience under one of the most extraordinary phases of mental derangement, entitles me to some attention on that special subject; this however, from the first, I have never expected in this generation, except from men like Dr. Esquirolle or Dr. Conolly. Mankind in these matters are still labouring under the same folly which has impeded their advance in all sciences, and the opinions and observations of Commissioners on Lunacy, of lunatic doctors, and even of medical men who have little practical acquaintance with the subject, are the sole authorities looked to, almost to the exclusion of the testimony and experience of their unfortunate victims; yet if I had to lead a body of troops through an unknown country, I would rather depend, for the details of every day's march, upon the information even of the savage inhabitants, than on the books of travellers and the maps of geographers, although it would be right to attend to their data and information to prevent deception.

If, as E. B. reminds your readers, there is a zeal without knowledge, there is also a presumption that our knowledge is perfect, and that we form unerring conclusions from our observations, which excludes knowledge, and consecrates unsound principles. Of all classes of men—the owners of private asylums—who for ages have been confessedly labouring in the dark, and into whose institutions light has only broken within the last thirty years, are the last that should expect confidence in their opinions, when we know how they abused the implicit confidence they formerly laid claim to, and to which they required relatives to surrender their unfortunate patients. I have often doubted whether, as E. B. states, personal restraint should not be allowed, if not too protracted, in suicidal cases, and in cases where the patients, from delusion, or from savage impetus, are likely to do themselves or others injury; but it is a debateable question, and, I have been answered, that the apparent necessity for it arises from defect in the management of the patients. I am little acquainted with those cases where restraint is required for moral objects, but in some of these, perhaps, a more liberal construction of the rules of religion and morality, which are evidently not intended to be of universal application, might be certainly more wholesome and more beneficial, if by that means the patients could be weaned from the abuse, to the use, of Nature's laws and propensities. This, however, is, I confess, a very delicate and very difficult subject, and involves a great revolution of opinion amongst those who hold pharisaical doctrines, or austere notions on the subject of religion. The separation of the sexes is, in my opinion, the most cruel and fearful consequence of all confinement, and cannot but greatly contribute to the maladies and miseries, and retard the prospects of recovery, of the insane.

I have the honour to be, Sir,

Your obedient humble servant,

JOHN PERCEVAL.

Kensington, April 9, 1852.

Medical Intelligence.

COLCHESTER MEDICAL SOCIETY.

At a meeting of the Colchester Medical Society, it was unanimously resolved,—“That the members of the Colchester Medical Society pledge themselves not to meet professionally any person practising homœopathy, or homœopathy combined with rational medicine; and that any member of the Society violating this pledge will be considered by the Society, as acting *unprofessionally*. That a copy of this resolution be sent to every member of the Society.”

MEDICAL BENEVOLENT COLLEGE.

At a meeting of the Council of the Medical Benevolent College, held at the Hanover Square Rooms, on the 6th instant, Dr. Watson was unanimously elected Vice-President of the College. The Rev. Henry Mackenzie, Vicar of St. Martin's-in-the-Fields, and the Rev. H. Glossop, Vicar of Isleworth, were also elected life governors of the institution, both these gentlemen having, in their respective districts, kindly preached in aid of the funds of the College.

ROYAL COLLEGE OF PHYSICIANS.

Dr. Paris, President; Dr. Wilson, Senior Censor; Dr. Hawkins, Registrar; Dr. Burrows, and Dr. Nairne, had an interview last Saturday with the Secretary of State.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted Fellows on the 5th and 7th instant:—Thomas Francis Fernandez, Madras Medical Establishment—Diploma dated Oct. 5, 1838; Thos. Eaton Lander, Shiffall, Shropshire—April 18, 1842; James Morris, Park Street, Grosvenor Square—June 16, 1848.

The following gentlemen were admitted members on the 16th instant:—Robert Thorley Bolton, Hexham, Australia; Henry Desplan, Bath; Edmund Adolphus Kirby, Hampstead Road; Henry John Hughes Lawrence, Carmarthen; Francis Nottidge Macnamara, Uxbridge, Middlesex; Francis Wm. Merry, Shottesham All Saints, Norfolk; James Barclay Montgomery, Penzance, Cornwall; George Newport Pickstock, Belize, Honduras, West Indies; Henry James Rogers, Peninsular and Oriental Service; John Kent Spender, Bath; Alonzo Henry Stocker, Grove Hall, Bow, Middlesex; Edwin Adolphus James Wilkinson, Birmingham.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on the 8th instant:—Frank Lane Bindley, Burton-on-Trent; George Smith Brent, 13, Caroline Street, Bedford Square; Erlin Clarke, Worcester; Ebenezer Davies, Swansea; James Ekin; John Fountain, Cowley, Uxbridge; John Northend Nicholls Hamerton, Elland, Yorkshire; John Roberts Hughes, Flintshire; Joseph King, Newbury; Robert Knaggs, Clapham; Joseph Lewis, Cardiff; Frederick Moon; Charles Palmer, Horton-in-Lindsey; Robert Bryant Pearse, Bath; Thomas James Vallance; Geo. Walker, Harworth-on-Tees, Durham; Charles White, Doncaster.

Gentlemen admitted members on the 15th instant:—Robert Cuff, Northbury, Somersetshire; Thomas Wm.

John Goldsbro, Welshpool, Montgomery; John Hall; John Long, Leeds; John Thomas Muriel, Ely, Cambridgeshire; Richard Bird Nason, Nuneaton, Warwickshire; Henry Osborne, Northampton; Augustin Benoit Pettrau, London; Charles Sanders; John Charles Savery, Hastings; Henry Charles Warren, Milverton, Somersetshire; William Webb, Barton-under-Neewood; David Jones Whitty, Britonferry, Glamorganshire; Samuel Wright, Huntingdon.

UNIVERSITY AND KING'S COLLEGE, ABERDEEN.

GRADUATES OF M.D., APRIL 15, 1852.—Christopher A. Allen, Cork; Philip Brown, Durham County; George Crosland, York-shire; Ernest Elliott, Portsmouth; John Dalston Jones, London; Robert Molloy, Pentonville, London; William Home Popham, London; Owen Richards, Cardiganshire; James Ross, Elgin; James William Young, County Meath, Ireland.

APPOINTMENTS.

Mr. John Wickham Barnes (of Bath) has been appointed House-Surgeon to the Royal Westminster Ophthalmic Hospital.

Mr. E. Pitt has been appointed House-Surgeon to the Wrexham Infirmary.

Mr. Samuel Wall has been appointed Colonial Surgeon at the Gold Coast.

Dr. Millington, of Queen's College, Birmingham, has been appointed Surgeon to the Staffordshire General Hospital.

Mr. Hunter, Mr. Hoffman, Mr. Price, and Mr. Waddington, have been elected Consulting-Surgeons to the Margate Sea-Bathing Infirmary.

Mr. Miles O'Brien has been appointed Apothecary to the Newcastle Dispensary, under the Medical Charities' Act.

BOOKS RECEIVED FOR REVIEW.

Observations in Surgery. By Benjamin Travers, jun., Esq., F.R.C.S. London: Longman and Co. 8vo, pp. 230. 1852.

The Pathology and Treatment of Stricture of the Urethra. By John Harrison, Esq., F.R.C.S. London: John Churchill. 8vo, pp. 104. (Plates.) 1852.

Hydrophobia, as Applied to Acute Disease. By T. R. Armitage, M.B., Lond., M.R.C.S. London: John Churchill. 8vo, pp. 178. 1852.

TO CORRESPONDENTS.

Communications have been received from Dr. Hall, Mr. Wood, Mr. Solomon, Mr. Gabb, Mr. Walker, Mr. Sands Cox.

We have received several private letters on Mr. Pascoe's case, all condemning the verdict and suggesting applications to the Secretary of State. We believe that the case is now undergoing a searching investigation. This we hope will result in a reversal of the sentence, which to us certainly appears totally unsupported by any evidence worthy of credit.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

THE NEW EQUITABLE LIFE-ASSURANCE COMPANY.

POLICIES INDISPUTABLE.

INCORPORATED BY ACT OF PARLIAMENT, 7 AND 8 VIC., CAP. 110.

TRUSTEES.

SIR JAMES DUKE, Bart., Alderman, M.P. for the City of London.	GEORGE JAMES GUTHRIE, Esq., F.R.S., late President of the Royal College of Surgeons; Consulting-Surgeon to the Westminster Hospital.
JAMES WYLD, Esq., M.P. for Bodmin.	SIR CHARLES HASTINGS, M.D., Founder of the Provincial Medical and Surgical Association of England, and President of the Council.
WILLIAM FERGUSSON, Esq., F.R.S., Surgeon in Ordinary to H.R.H. Prince Albert; Professor of Surgery to King's College, London.	

DIRECTORS.

CHAIRMAN OF THE BOARD.

ROBERT LEE, M.D., F.R.S., Savile Row, Burlington Gardens.

DEPUTY CHAIRMAN.

GEORGE BEAMAN, Esq., M.R.C.S., King Street, Covent Garden, and Hampton Wick.

CONSULTING PHYSICIANS.

MARSHALL HALL, M.D., F.R.S., Grosvenor Street, Grosvenor Square.	CHARLES J. B. WILLIAMS, M.D., F.R.S., Holles Street, Cavendish Square.
JAS. ARTHUR WILSON, M.D., Dover Street, Piccadilly.	

CONSULTING SURGEONS.

WILLIAM FERGUSSON, Esq., F.R.S., George Street, Hanover Square.	J. RANALD MARTIN, Esq., F.R.S., Grosvenor Street, Grosvenor Square.
SAMUEL SOLLY, Esq., F.R.S., St. Helen's Place, City.	

SURGEON AND MEDICAL EXAMINER.

THOMAS WAKLEY, Esq., F.R.C.S., Guildford Street, Russell Square.

STANDING COUNSEL.

SIR ALEXANDER COCKBURN.	GEORGE WOODYATT HASTINGS, Esq., Paper Buildings, Temple.

BANKERS.

THE COMMERCIAL BANK OF LONDON.

CONSTITUTION AND REGULATIONS OF THE COMPANY.

CAPITAL.—MUTUAL ASSURANCE.

The "NEW EQUITABLE" embraces all the advantages of a strictly Mutual Office, with the addition of an ample subscribed paid-up capital, forming a *bonâ fide* security for its policy-holders.

POLICIES INDISPUTABLE.

The Policies of this Company being Indisputable, they become as readily negociable, in monetary transactions, as any other description of personal property.

INVALID LIVES

Are assured at rates adapted to the circumstances of each case. Every circumstance affecting the health impartially considered.

DIVISION AND APPROPRIATION OF PROFITS.

The whole of the Profits will be Equitably Divided amongst the holders of Policies issued on the participating scale.

MEDICAL PRACTITIONERS.

The Directors acknowledge and consult all duly qualified Medical Referees as the Medical Advisers of the Company, and uniformly transmit, with the Questions intended to be made the basis of every Official Medical Report, A CONSULTATION FEE OF TWO GUINEAS.

Extract from the Directors' Annual Report.

"The Directors of the New EQUITABLE believed that, by adopting a plan founded on justness and liberality towards the Medical Profession, an immense field hitherto uncultivated would be opened for philanthropic and prudential operations. The position thus discovered and examined they have attempted to occupy, and abundant are the reasons which render the results pre-eminently satisfactory.

"The business already transacted by the New EQUITABLE Company has exceeded, both in extent and character, the most sanguine expectations of its founder and zealous advocates. From the 31st of January, 1851, the date of the complete registration of the Company, to the 31st of January, 1852, inclusive, no less than four hundred and forty-eight proposals were received and entertained by the Directors. Out of this number of proposals three hundred and fifty-five policies were completed, and the remaining ninety-three have been either declined, or are not yet completed. The sum assured on the three hundred and fifty-five policies issued by the Company is one hundred and sixty-eight thousand seven hundred and sixty-five pounds. The premiums on the policies thus effected amount to six thousand and twenty-five pounds two shillings and seven-pence per annum, the average amount of the policies being nearly five hundred pounds."

Forms of Proposals, and any further information, may be had on applying personally, or by letter, to the Resident Director or Secretary, at the

CHIEF OFFICES, 449, WEST STRAND, CHARING CROSS, LONDON.

MEDICAL BENEVOLENT FUND.

TO RELIEVE BY GRANTS AND ANNUITIES THE MEDICAL MAN, HIS WIDOW OR ORPHANS, IN SICKNESS AND DISTRESS.

THE DINNER in behalf of this FUND will take place at the LONDON TAVERN, on THURSDAY, MAY 20th,

THE RIGHT HON. THE EARL OF CARLISLE IN THE CHAIR.

CLINICAL LECTURES
ON THE
PRACTICE OF PHYSIC,

DELIVERED IN THE
THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D., EDIN.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c.

LECTURE XV.

ON THE MORBID CONDITIONS OF THE URINARY
ORGANS CONTINUED.

GENTLEMEN,—In our last lecture we took a review of the nervous or functional derangements of these organs, and their treatment; and we also dwelt upon the nature and management of acute and chronic inflammations. I now direct your attention to the more frequent, and, upon the whole, more dangerous and fatal disorders, arising from congestion and degeneration.

CONGESTION, by which is to be understood a distention of vessels, and a sluggishness of circulation, commencing in a stagnation of the venous and capillary blood, is a very common occurrence in the kidneys. Nor does the frequency of such a morbid condition surprise us, when we consider that there are such various causes for determination of blood to the kidneys. For they are not only designed for their own peculiar and exclusive purposes, but they are also vicarious to other organs, when these may be checked in the performance of their functions. Thus, besides the extraordinary efforts which they must necessarily make, whenever either the increment or the waste of the body, very much exceeds the usual amount, they have likewise to be tasked in a more unnatural way, so soon as the skin, the liver, or the bowels are interrupted in their duties. Under all such circumstances—and they are exceedingly numerous—the vessels of the kidneys at once become gorged and distended, and if this continue beyond a certain period, or be carried to an extreme, it must necessarily happen that the elasticity or organic contractility, will be more or less overcome and destroyed, so that the vessels will be brought to a condition of permanent relaxation, which will make them habitually yield to still lesser degrees of pressure. At every successive engorgement this state of things will be increased, if it does not, indeed, lead to a continual state of congestion, itself a disease, but yet tending to bring about other diseases of a still more deep and serious nature. Also, besides these functional causes of renal congestion, there may be others of a more mechanical kind, such as the pressure of tumours, or calculi, or of dropsies, or external injuries. And all this will be still more apparent to you, when these various causes are further particularised—such as eating beyond the requirements of nature, and indulging in excess of compound drinks, especially when this is done as a matter of habit. Also any excessive disintegration of the tissues under fatigue

of body and mind, or the presence of such consuming or destructive diseases as inflammations, ulcerations, and fevers. Then we have to consider the sundry foreign matters that may be assumed by the mouth, or generated in the blood, and which must find an outlet by these organs; as well as the revulsed excretions of the skin, the liver, and the lungs, occurring under extreme cold, or under some regular affections of these parts. When you consider, I say, all these circumstances, you need not feel surprised that congestion of the kidneys is a common event. When it occurs suddenly, from any unwonted cause, the local symptoms will be pretty manifest, and the patient's observation will scarcely fail to be directed to the subacute heavy pain in the loins, along with the scantiness or over abundance of urine, abounding in thick deposits. If, however, it be of gradual accession, as it commonly is, the pain will consist more of a sense of heaviness in the part, and in a general lassitude such as may not excite his particular attention, until they have so oppressed him, that his life has become burdensome, or some secondary disease of a worse character has been induced, as diabetes, or albuminuria, or general dropsy.

From these observations you will infer that I wish to draw your special attention to this condition of the kidneys, and the more so from the symptoms often being so obscure. No patient should pass without some inquiry into these matters, for you know not in how many instances it may be the means of warding off such painful diseases as gout and rheumatism, and such a fatal one as albuminuria. To this end you should apply gentle but deep pressure over the organs, without any sudden poking or grasping, and learn if there be any uneasiness experienced. You may also desire the patient to lift something that tasks his strength, and watch if there be any stiffness or shrinking of the loins. If circumstances permit, you may likewise examine the skin of the loins, and see if it be of a deeper colour than natural, if the veins seem loaded, or if the blood that may be drawn from them be thick, dark, and tarry. You will note whether the sufferers have an unaccountable languor, drowsiness, and disinclination to exertion, and whether their ordinary labours may induce weakness in the back, and compel them to resort to such undesirable articles of dress as belts, long stays, and paddings, for the sake of mere support, and apart from any affections of imagined grace or beauty. You will also specially examine the urine, as to its amount, colour, and density, its deposition of sundry salts, and its intermixture with blood globules, pus corpuscles, albumen, fibrin, or any extraordinary amount of mucus. Not until you are satisfied on these points, will you be justified in treating such a patient for those vague ailments, which are too often carelessly denominated dyspepsia, change of life, cachexy, debility, and so on, for which you would forthwith be administering tonics, and bitters, with mineral acids or alkalies, as the case might be. Under such circumstances these remedies may tend only to increase the evil, and you will be subjected to the annoyance of your patient constantly repeating the same complaints of

lassitude, weight, and general derangement of health, in spite of the whole armarium which you have brought to bear upon his case. Doubtless, from the deposits in the urine, you may be led to combine with the above medicines, diuretics, alteratives, and diaphoretics, which are very desirable at the proper time, and under the right circumstances; but you may also find that these have by no means the effects which you anticipated, and, simply, because all your diuretics and alteratives can have no free play, while this physical condition of the kidneys is acting as an impediment to their operation. It must be evident to you upon a little reflection, that all this increased injection of foreign matters, such as your nitrous æther, your juniper, or your Hollands; your highly nitrogenated tonics and meat diets; your soda, potass, or ammonia, cannot at all remove the one essential and fundamental cause of all the evils—viz., the congestion or engorgement; but will rather throw an additional burden of excretion upon that member, which is already unable to eliminate even the natural waste of the body, and, therefore, you will find that, so far from the appetite improving, or the strength increasing, or the body becoming lighter in its feelings, all the uneasy symptoms will advance and deepen. The food will be still more loathed; the mouth will become more conscious of an offensive urinous or metallic taste; the skin will be subject to sweatings, instead of the natural and invisible transpiration; the whole frame will become more conscious of languor, and the mind more dull and depressed.

The same condition of congestion existing in the ureters or bladder, would require similar management; but the symptoms and effects would be by no means of the same consequence there as in the kidneys, and therefore I shall at once proceed to speak of the treatment of renal congestion, without dwelling upon these minor parts at all.

And, in the first place, I must say, that whatever may be the internal remedies required in this or that peculiar case of congestion, all such remedies, to be properly effectual, must be preceded by local abstraction of blood. It is the engorgement of the vessels with a deteriorated blood, and the consequent unnatural pressure upon the excernant structures and their organic nervous filaments, that prevent them from performing their functions; and, as I have shown that the additional assumption of foreign, and especially saline and nitrogenated elements, must tend further to deteriorate the blood, and to increase the burden and pressure that already weigh upon the renal excernants, it is clear that all such matters must do harm rather than good. To relieve the nervous filaments of this paralyzing pressure, to unload the capillaries and other vessels of their distending fluids, to excite the former to renewed vivacity and the latter to renewed contractile energy, are the first indications, and these can only be accomplished simply and speedily by a removal of the direct cause, which is this overplus of blood. When that is removed, and free play thus allowed to the nerves, vessels, and excernant cells of the organ, your renal stimulants, tonics, and alterants may then be

poured in with good effect, but certainly not till then. To this end, cuppings or leechings will be the best appliances, along with those purgatives which would act most briskly upon the bowels. To resort, as a usual rule, to general bleeding, would be improper, as the state of the system might forbid it; although in a very plethoric and apoplectic subject, that measure might be not inadmissible. But no such objection can be urged against local bleedings, except by those who adopt the sweeping dictum that no blood should ever be removed at all. Such persons commence their reasoning with the declarations, that physicians ought only to assist nature, and that nature never resorts to blood-letting. The first assertion is agreeable to reason, but the second is palpably false, as witnessed in natural bleedings at the nose, in piles, and in the female catamenia; such natural hæmorrhage always being the result of local turgidity of the vessels containing deteriorated blood. But, even if this were not the fact, we must recollect that nature can go wrong as well as right; and, if she did not do so, then there were no use of physicians at all. Yet, in truth, when either nature or the physician resorts to local depletion, it is not proper reparative blood that is drawn off; but something that is not only useless, but vitiated, and hurtful to the constitution. Such fluid, by its stagnation, and the chemical changes consequent upon the depression of vital action, has become quite unfit to be taken back into the system with advantage, and is, therefore, better removed, as only affording a fit sphere for the morbid separation, or formation, of fibrin, fat, albumen, tubercle, and other results of altered affinities and diminished vital energy in the blood. These different deposits will severally accrue from congestion, according to the nature of the patient's constitution; fibrin in the robust and plethoric; fat, tubercle, and albumen in the scrofulous; and colloid and cancer amongst persons of a malignant diathesis. Such facts all point to the timely removal of stagnant and degenerate blood, before proceeding to the employment of other remedies.

The kidneys, then, being thus cleared of their unnatural load, our next steps must be to excite the organic nerves, to constrict the relaxed vessels, and to eliminate those matters from the system which have hitherto been retarded in their excretion, and produced a long series, perhaps, of secondary and tertiary ailments, such as anorexia, albuminuria, and dropsy, with rheumatism, and other local inflammations. It may also happen that we have to supply certain elements which may have become deficient during a lengthened period of mal-assimilation. The best stimulants for these nerves are lytta, nitrous æther, juniper, and the rest of that class of diuretics; for constriction of the vessels we have various saline astringents, such as acetate of lead, &c.; but the most appropriate for the urinary organs are the bucu, the uva ursi, and the terebinthines; to alter and amend the urinary elements in the blood, and promote their excretion, we have colchicum, with acids, or alkalies, according to the particular conditions of the blood; and we have also those salines which are solvents of the earthy

principles, such as phosphate of soda, or of the fibrin, such as nitrate of potassa. The employment of these three classes of remedies, along with the occasional abstraction of blood, is what is regularly required in every case of renal congestion; the extent of their employment being alone the consideration in any constitution. But, besides these, there are other additional agents, which would be specially applicable in certain special cases. Thus, colchicum, and the ordinary chemical neutralisers, would be enough for any ordinary manifestation of the disease, as in chronic renal rheumatism and the like; but if the patient were of a plethoric, and inflammatory habit, with fibrinous blood, as in acute rheumatism, then calomel and nitrate of potassa were desirable additions; if a fatty habit existed, potassa before food, and super-muriated iron after it, might be advisable; in a thin, scrofulous patient, we might employ the cod oil and its adjuncts; and, in an anæmic or otherwise degenerate person, the carbonate of iron, or phosphates of iron and lime. Where albumen was escaping, we would have as plain an indication for the supply of it to the body, in the shape of eggs, &c., as we have indications for the supply of oil and iron in the consumptive and anæmic. But, whatever else we may do, let me only repeat once more, that we must relieve the gland of its oppressive load, excite the functional activity by specific stimulation, aid the vessels in resuming their natural contractility, and give full attention to the excretion of all the effete elements of the body, not merely by means of the kidneys, but by the bowels, the skin, and the lungs.

I have dwelt thus particularly upon this disorder, because I believe it to be not only very common, but also very often overlooked; and when we find its long continuance to be so frequent a cause of those terrible degenerations which we are next to consider, I feel that I should be wanting in my duty if I did not rather run the risk of being thought prolix, than not sufficiently force it upon your attention. I shall now adduce one case of this malady as an example, but need not cite more; because they are scarcely required to illustrate a subject so clearly physiological and deductive, apart from all experience. Besides this, such cases are seldom severe enough, when not complicated with the secondary results, to come into the hospital; but you have frequently witnessed them amongst out-patients, and so-called dyspeptics and cachectics, in which I have ordered the loins to be cupped or leeches, with remarkably favourable results almost immediately following therefrom, and all traceable to a freer expulsion of the urinary elements from the blood.

You will recollect the case of nurse ABBOTT in the hospital. She had long been subject to lumbar pain, which had become much aggravated for three months before she placed herself under me. Some time before, Mr. Moore, to whom she complained, found the urine much loaded with lithates, and, at that period, she obtained relief from alkalies and benzoic acid. The pain, however, had returned in force, and, on examination, her brow was observed to exhibit an expression of continued organic suffering. She had heavy and severe

pain in the loins, increased upon motion; the tongue was foul; the appetite gone, and the sleep disturbed; the urine was very red and scanty, and the pulse 120. The first thing now done was to cup her in the back, and she then had colchicum and muriate of morphia in an alkaline mixture. By the next day the pain was easier, though the urine was still red; and she also passed gravelly particles, like the dust of cayenne pepper, and so she gradually improved and recovered. Other complications arose in the course of the illness, such as torpitude of the liver, and bronchitis, but, at the end of a month, she had no pain, her urine was natural, she eat and slept well, and was quite active, and free from the perpendicular wrinkles.

There could be little doubt that the chief source of benefit in this case was the cupping, which I do believe would, in many instances, effect all that we desired, even without the aid of anything else beyond the *vis medicatrix nature*.

The DEGENERATIONS which overtake the kidneys are, like the degenerations in other parts, always referable to morbid conditions of the blood, and shall be treated of as to their origin and advancement at another period of the course. At the same time, there are some of those affections so important in a practical point of view, and so well exemplified by what we have seen, and now see, in the hospital, that it is advisable we should review them at this time, though not so much as regards theory, as practice and demonstration.

The MELLITIC DIABETES is so constantly, as one might almost say, connected with congestion of the kidneys, that I naturally allude to it first in connection with this affection, although its actual nature, in a pathological view, is still as great a mystery as ever. Sometimes, it would seem chiefly to have proceeded from a defect of energy in the organs of primary assimilation, the carbonized ingesta having proceeded no further than to form sugar, absorbed as such, and expelled through the kidneys, thereby inducing renal congestion only as a secondary effect. At other times, however, the sugar has not been detected in the blood, and seemed rather to have been matured in the kidneys, which, in such cases, have been found enlarged and congested; but, as in either circumstance, the real causes of arrest or of morbid change in the assimilative and excreting processes are quite unknown, it would serve no useful purpose to speculate upon the many suppositions that have been pushed forward by different writers. I quite coincide with Dr. Graves in thinking that each different view is as well supported as another, and that all of them are contradictory to each other, and unsatisfactory; and, although it may seem over-cautious, and equally unsatisfactory, that one should give no opinion about it at all, yet we thereby escape from the danger that always attends the advancement of mere suppositions—viz., that we are thus apt to think that we know something, when we know nothing, and so rest contented with our ignorance. Dr. Graves admits, as we all must admit, that the amylaceous elements, being arrested at the saccharine stage of their transformation, will be taken into the blood, and dis-

charged by the kidneys; and he does not doubt but that many people who are commonly ranked under the general name of dyspeptics, do thus excrete a urine partially charged with saccharine matter, which is no uncommon event, while genuine diabetes is very uncommon. But, at the same time, such a condition of the blood is no certain result of indigestion; and Dr. Graves sees no reason, nor do I, why the kidneys, under some perversion of function, may not themselves play some part in the creation of sugar—a substance, as he justly remarks, so readily formed, even by organizations of the lowest order; at all events, as we cannot as yet trace the order of events to their primary source, we are not in a condition to offer any scientific plan of treatment, such as may reach the essence of the morbid action. We combat collateral symptoms, and meet particular defects and excesses, but we can do no more. You are aware that the great symptom is the discharge of sugar by the urine, which not only flows in vast abundance, but is also marked by an increase of its specific gravity, which reaches even so high as 1050, while, perhaps, the proper urinary salts are in deficiency. This symptom is always accompanied by a voracious appetite, and derangement of the stomach, and almost always, from the beginning, with congested kidneys, hypertrophied in all their tissues. The papillæ of the tongue are uncommonly long, and sometimes brown or black; there is a mellitic odour in the breath; emaciation and debility, with languor and indifference, soon set in, all ending, very frequently, in pulmonary consumption. There being no certain theory to connect all these results, the consequence is, as I say, that we have no certain or philosophical treatment. We combat this or that derangement as it presents itself to our senses, but can point out no leading or fundamental rule; and the fact stands plainly before us, that although various pretenders, from time to time—perhaps magnifying the partial and fluctuating discharges already mentioned into real examples of diabetes—have arrogated to themselves the cure of this as of other mysterious diseases, we have no record of any scientific physician having asserted that he arrested this malady by any scientific treatment, and those recoveries that have taken place, have appeared to be the work of natural and accidental causes, or the merely happy result of that assiduous attention to the general health, and to this or that symptom as it arose, and not to any specific plan of arrest, founded upon principle. Thus, seeing that the sugar can be formed from starch alone, there is a clear indication for the withholding of such a substance, and the giving rather a nitrogenated diet; yet not that this measure affects the real disease, except by relieving the kidneys of their burden. Likewise, as these latter organs are congested, blood may be rationally withdrawn from them, and astringents used, and yet this congestion alone does not constitute the diabetes. The stomach and bowels being, at the same time, torpid and inefficient, we may attempt to check the saccharine formations by stimulation, and invigorating tonics, yet not that such formations are the invariable and necessary consequence of the debility, or that the tonics and

stimulants will, with any certainty, check the morbid action. Lastly, the skin being almost always dry and torpid, diaphoretics are properly resorted to; but no one ever imagined diabetes to be an ailment of the skin, or that the restoration of the dermic functions would, *per se*, cure the disease. The only article of the *materia medica* that ever did seem to me to act in any specific manner, by checking the unnatural discharges, was lime, but, at the same time, it has also appeared to aggravate the constitutional uneasiness, and to beget a degree of irritation which the ordinary sedatives could not assuage.

HENRY SIMMONS, who was lately in the hospital, had been ill for about two years, and had during that time, wandered about the country from hospital to hospital. He had lost much flesh, and discharged twelve pints of urine daily, of specific gravity 1030. His pulse was 120; his tongue was black in the centre; he had very acid vomitings, with epigastric tenderness; and his skin was scurfy, and dry. He first had an emetic, followed by a purge, and then a blister was applied to the epigastrium, while he took bismuth and magnesia in an infusion of calumba. The blister took no effect, but the sickness was relieved. The urine, upon trial, fermented freely, and, after evaporation and digestion in alcohol, six ounces of it yielded 192 grains of solid matter, containing upwards of one drachm of sugar. He now had *potassa fusa* applied to the epigastrium, and took, besides the above medicines, ammonia and Huxham's tincture of bark, under which the tongue became gradually cleaner, and exhibited white papillæ, of extraordinary length and flaccidity. The urine also came down to eight pints. He subsequently was leached in the loins, and took varieties of stomachic stimulants and general tonics, such as quinine, arsenic, strychnia, and so on, along with astringents, but with no great alteration in the essential symptoms. He left the hospital as he entered it, so far as the diabetes was concerned; though certainly much relieved from a variety of distressing accompaniments in the stomach and other organs.

And such is the ordinary history of the disease. We have no records, as I have said, of cases of recovery in which any specific remedies that were employed could be depended on as serving the same end in the next case that presented itself, far less in a consecutive series of cases. These are the order of maladies that deserve to be closely watched from beginning to end, in hospitals specially devoted to these and other such mortal affections; for it is only from the concentration and continuance of observations that we can expect to unravel any really available and leading doctrines for practice from such an interwisted puzzle of symptoms; while little is to be expected from the occasional and interrupted study of individual patients over whom you cannot always command a perfect control. That the disorder proceeds from some secret changes in the ganglionic innervation and extreme capillaries of the general system, there can be little doubt, for, if it were merely a concomitant of ordinary or primary indigestion, or of congested kidneys, it would be much more common, and would not prove the terrible disease that it is;

neither would we see the patients dying in the extremity of bodily waste and mental misery, without, perhaps, exhibiting in their bodies any visible change whatever, except a deposit of granular matter in the lungs, and sometimes not even that.

THE GRANULAR DEGENERATION, since its precise nature was demonstrated by Dr. Bright, is now found to be a comparatively common disease, existing, to a greater or less extent, in numbers of subjects, though not, perhaps, except in a few, manifesting itself in a decidedly severe form. It consists essentially of a deposit of foreign matter of low organization, within the proper tissues of the kidneys, which thus become atrophied and ultimately absorbed. These deposits, having no power to assume the glandular functions—although so far lying within, and having the rude form of a glandular apparatus—are not calculated to eliminate those excretions which ought thence to be drained, without, at the same time, showing a tendency to permit the most valuable reparative material in the blood (albumen) to escape along with them; and hence the common name of this complaint, from its principal symptom—albuminuria. It has been ranked as a disease of the blood; but we do not usually find any decided manifestation of it except in connection with physical disorganization of the kidney; and it would, I suspect, be extremely difficult to point out any very tangible changes in the blood prior to this disorganization taking place. No doubt the red particles are always defective under such discharges of albumen; but that may be as much a consequence as a cause of the disease; though it must be admitted that the occasional manifestations of profuse albuminuria, as a mere passing symptom, in the course of other diseases tending to debilitate the nervous system and attenuate the blood, affords proof that it is possible to be sometimes a simply functional or accidental filtration of the nutrient fluids. The degenerations of structure, though all ranked under the one complimentary name of the *Brightian disease*, may be of various kinds, according to the constitution of the patient, and the nature of the inducing causes; and, though the most prevailing of these causes are impoverishment and debility of the body, proceeding from the scrofulous or syphilitic taint, anæmia, habits of excessive drinking, or the abuse of mercury; yet another order of causes are to be looked for in the form of local or accidental affections, such as the kidneys are subject to in common with other parts. Thus, without finding any prior deterioration of the blood, or any evidence of a preceding local hyperæmia, we may be compelled to look for the primary source of the disorder in a simple perversion of function in the renal nerves, by which the natural vital reaction is so modified, and the affinities so altered, that instead of glandular or epithelial cells being formed and deposited as usual, we shall have a displacement of them by means of granular or tubercular matter, or fat. Here we should have no previous pressure, followed by absorption, but a simple death and disappearance of the higher order of structures, and a substitution of degenerate matters in their place. Nextly, the evil may proceed from a simple anæmia, in

which the over-fibrinated blood may block up and ultimately obliterate the extreme vessels, thus cutting off the source of nutriment from the glandular structure, and substituting in its stead an impoverished lymph, destined, perhaps, to undergo still deeper degenerations in the course of time. Also, we may have a protracted congestion, pressing upon the nervous filaments and delicate microscopic structures of the organs, thereby lowering their vitality, and preparing them to yield, without resistance, to the morbid precipitations which are sure to proceed from a vitiated and stagnant composite fluid like the blood. Then, we may have a subacute inflammation, acting in a manner pretty similar to anæmia, so far as effects are considered, but more rapidly and expansively, in which large amounts of fibrinous exudation will be poured out, oppressing the proper structures, and leading to their destruction, while itself ultimately sinks into a lower form of organization, and becomes the nidus of those fatty or tubercular depositions which are the last evidences of this terrible malady. Such secondary degenerations will be modified by the constitutional diathesis of each patient. Thus, in the more healthy habit, where the disease has rather proceeded from some accidental anæmia or local inflammation, we may only have a fibrinous or carnified kidney, without fat or tubercle; whereas, in the fatty habit, we shall have a sebaceous deposit, and, in the scrofulous or syphilitic patient, a mere granular debris, either generally diffused or aggregated into larger or smaller masses, and perhaps intermixed with pus. Under any circumstances, some degree of chronic inflammatory action must arise, if not as a primary cause, yet certainly as a consequence of the irritative deposits; and hence there will always be found gluings or adhesions of the different structures, especially witnessed in the close attachment which takes place between the fibrous capsule and the organ proper, from which it naturally peels off in a clean manner; whereas, in this disease, it is generally difficult to detach it, without also tearing off sundry portions of the mollified gland. In all cases, likewise, there will be found an obliteration of the vessels, so that the organ cannot be properly injected.

Now, besides the leading, though not altogether unexceptional, feature of albuminuria, the symptoms that will appear, in most cases, are dull pains in the loins, inclination to drowsiness, frequent but scanty micturition, nausea and epigastric tenderness, anasarca or general dropsy, and a pale puffy aspect of the countenance and flabbiness of the limbs, concomitant with deficiency of the red particles of the blood. This latter mark of the disease, giving a Flemish expression to persons in this country, is a very valuable one, for it will often give us a clue to the malady before its more annoying symptoms excite attention; so much so, that the eye of the experienced physician sometimes draws its conclusions from the physiognomy alone. And I am the more satisfied of its value, because I have often found that it revealed the secret of renal disease, as proved after death, even when there was no albumen to be detected in the urine during life. Such evidences of morbid action

must always be duly attended to; and we must recollect that, though it was chiefly through such empirical signs that the ancients attained to the art of diagnosing and curing diseases, such a habit, in the absence of more positive knowledge, did not prevent them from becoming excellent physicians. We arrive at our diagnosis by shorter and more certain methods of inquiry, and we also cure upon more rational and obvious modes of treatment; but yet the empirical mode of observation and healing is never to be lost sight of; because it does very often avail us in obscure cases, in which the rational signs are not very apparent, and the so-called rational remedies disappoint us. I say *so-called* rational remedies; for, indeed, almost all the appliances of therapeutics, unless you except those which act chemically, are essentially empirical; that is, they are known to act in a certain way by experience alone, and not by any rational recognition of the natural connection between them, as causes, and their physiological effects. Indeed, we cannot even except the chemical agents from this empirical category, inasmuch as it is only by observation and experiment, and not by abstract reasoning, that we learn of an alkali neutralising an acid. The like observations and experiments teach us that opium neutralises pain, and that antimony causes vomiting, and colocynth purging, &c.; but while we are apt to designate the latter as empirical, and the former as rational, appliances, we must recollect that we have just the same grounds of reason for using the one as the other. In truth, it suited the purposes of scholastic disputants, at one time, to draw this marked distinction; but, after all, it is a distinction without a real difference; and he will be the most competent for the duties of his calling who combines the excellencies of both sects; that is to say, he who brings the highest degree of metaphysical or mathematical reasoning to generalize upon the details of the empirical or experimental sciences; for the two words are synonymous, except by overstrained interpretation. So much for the value of obscure and unexplainable symptoms in disease, such as this Brightian countenance, or the puffings of apoplexy, or the pickings at the bedclothes in brain disease.

As to the treatment of this granular or fatty degeneration, it must necessarily be varied, according to the various causes from which it may seem to spring, the varied forms which it may assume, and the various consequences to which it may have led. Thus, when the cause appears to be a general debility, it will require to be met by the invigorating remedies, and the usual routine of the tonic regimen, including sound diet, regular moderate exercise, and free exposure to the open air, when mild and sunny. If the atrophied form of scrofula be observable, oils and steel will be required; and, if the degeneration be of a fatty kind, potassa and the super-muriated iron may be advisable for alternate use. A syphilitic condition, or one arising from the abuse of mercury being visible, we should then resort to such diaphoretics as sarsaparilla and mezereon, with iodide of potassium. If habits of excessive drinking have been the cause,

these must be gradually checked; and, if the patient have suffered from anæmia, the blood-forming elements must be exhibited under as favourable conditions for appropriation as possible; and these would consist of the albuminous compounds, along with some excess of oil, iron, and the calcareous phosphate. Yet, while each case would be thus modified in its treatment by the apparent prevailing cause, we would require to look closely to the local conditions or causes, and to such secondary or tertiary symptoms as might have arisen in the course of the malady. A very simple and unvarying formula was at one time in general vogue, arising from the frequent use of it by Dr. Bright, when he had bent his attention to this disease, and published the results. I mean carbonate of soda, with conium, in some stomachic and diuretic vehicle. But I apprehend, from the additional illustrations of the rise and progress of this disorder which have been offered since the great discovery of Dr. Bright, that the remedies are now much more multiplied, not from the mere caprice of individuals, but from the perception of their fitness to certain varying pathological conditions. Thus, under the dropsies that generally arise, some would formerly have totally forbidden the slightest abstraction of blood, or the employment of diuretics—purgatives and sudorifics alone being by them admissible, no matter what were the conditions on which the dropsy depended. Whereas it is obvious, that if the kidneys be not too irritable, it is most likely that less harm will be done by expelling the accumulated waters through this channel for a short time, than by permitting them to remain as an oppressive load. And it is equally certain, as a matter of observation, that diuresis is a much less exhausting process to the constitution, even under such circumstances, than purgation, and that sweating is rather difficult to be produced, on account of the organic torpidity of the skin. Bloodletting is to be regulated by like considerations. Thus, where chronic inflammation or congestion seems to exist, cupping over the kidneys is to be by all means recommended, while, immediately afterwards, their irritability is to be subdued by a belladonna plaster, and the internal use of conium. In a fatty subject, such a course of cuppings may not be requisite, and potassa and conium may be rather employed; while in the tubercular form, accompanied with emaciation, oils may be directly beneficial, notwithstanding some prejudice against their use, arising from the narrow view of its being always a fatty degeneration and nothing else. In the early stage of such a type of albuminuria, renal stimulants may be advisable, while the uva ursi and other astringents, or acids, or alkalies, may be employed, according as there may be evidences of capillary relaxation, or of an acid or alkaline diathesis. Yet, in all cases whatever, as there is essentially a great tendency to loss of albumen from the system, and a deficiency of the blood-forming elements, so there is required, in conjunction with any other remedies employed, a very full supply of albumen in its most digestible form, which full supply must be accompanied by a more than usual supply of iron, and the calcareous phosphate. For the fuller and more precise illustra-

tion of these points of doctrine and practice, both as regards the essential and the accidental symptoms, I shall reserve the cases which we have had, and now have, in the hospital, as the subjects of another lecture. Such cases have been far advanced prior to admission, and our records, like those of others on the same disease, are, upon the whole, painful and deplorable; nevertheless, there are some encouraging facts to be stated, such as may incite us to a course of hopeful inquiry, not altogether useless.

OPHTHALMIC SKETCHES.

SHORT LECTURES

DELIVERED TO THE

STUDENTS ATTENDING THE BIRMINGHAM EYE INFIRMARY

By JAMES VOSE SOLOMON, M.R.C.S.,

One of the Surgeons to that Charity, lately Surgeon of the Birmingham General Dispensary.

LECTURE III.

Acute abscess of the cornea a result of the impaction of a foreign body in that membrane; the class of persons most disposed to this accident; treatment; terminations of abscess of the cornea; appearances in a part undergoing reparation, a change of treatment is now requisite; treatment of abscess of the cornea by puncture—by incision.

GENTLEMEN,—You will remember I have told you that foreign bodies may be removed from the cornea, either by the action of the palpebral muscles and a constant flow of tears, or, by the ulceration of the tissue immediately in contact with them, assisted by the preceding eliminants, or, by the interference of surgical art. In the event of the failure of the preceding natural processes, and of the patient's neglect to avail himself of professional aid, the inflammatory congestion of the conjunctival and sclerotic vessels, (that of the conjunctiva presenting an uniform deep red colour, the sclerotic a pink or lake colour, especially apparent around the margin of the cornea,) augments the exudation into the cornea, which at first thin, and superficially situated, as in Case 2, is now poured in considerable quantity into the lamellar interstices around the impacted foreign body, displacing and breaking down the natural structure of the part; the opacity thus formed is dense, white, elevated, and abruptly terminated at its margin, around which the cornea is less opaque. Amidst the exuded matter are formed pus corpuscles, and abscess of the cornea results: upon the ulceration of which the foreign body is discharged. An indelible opacity (leucoma) of greater or less extent will denote the site of the purulent collection ever afterwards. The majority of cases of abscess of the cornea, as a consequence of the cause we have been considering, you will find among careless, debauched men; or where the injury has been complicated by a severe blow upon the cornea. I have never had a single case in the person

of a Birmingham artisan, though the impaction of foreign bodies in the cornea is, with that class, a most frequent accident. I attribute this immunity to his facilities of obtaining well-directed surgical treatment, and to his excellent general health. The Birmingham mechanic is usually an intelligent man,* receives good wages, and is a resident of a healthy locality; he consumes a liberal quantity of animal food, and, though not a water drinker, is very seldom drunken, consequently with him diseased processes terminate favourably.

The indications of *treatment* are to obtain a subsidence of the ophthalmia, absorption of the purulent matter, and dilatation of the pupil. Exudation into the substance of the iris, consequently adhesion to the lens, is by no means an infrequent result of acute scleritis; it may take place very insidiously, with little if any perceptible change in the natural appearances of the former membrane. It will, therefore, be prudent practice to apply extract of belladonna to the brow, coating it over with glycerine to keep it moist, or the solution of atropine within the palpebræ, of the strength of one grain of the alkaloid to 200 grains of distilled water. Should the patient be robust, we bleed from the arm; even if he should not be so, the ophthalmia being acute, and accompanied by marked *febrile* disturbance, we adopt the same measure of relief. The patient should stand upright; a large opening having been made in the vein, you allow the stream to flow uninterruptedly, until pallidity of his lips, or a sensation of nausea, indicates that an impression is made upon the brain and heart. This is enough; we do not desire syncope. The patient should now be confined to his bed, the eyelids maintained closed, and the eyeball supported by a few turns of a fine *linen* roller, which is to be continually moistened with a belladonna lotion. Having premised a purgative, you commence with calomel and opium, repeating them every four hours, until the puriform matter evinces, by its diminution, the commencement of absorption. The patient is *not to be salivated*. An occasional morning purgative, by stimulating the organs of depuration, will promote the cure. If the patient has been bled early in the day, leeches or cupping glasses should be applied in the evening, otherwise on the following day. As soon as the active stage of the disease, indicated by the conjunctiva becoming pale red, has yielded to your measures, flying blisters will be advantageously employed to the temple. The local bleeding will generally, the blistering almost invariably, require repetition. The treatment apposite to cases in which the general power is feeble, or in which the ophthalmic affection presents a subacute character, will be delineated when I speak to you of contusions of the cornea.

* "Even during my short stay (at Birmingham) I could not help expressing my astonishment at the varied and complex information displayed by the superior workmen; for when I conversed with them upon the early history of their respective branches, they evinced a surprising acquaintance with the peculiar fabrics of Egypt and modern China. They spoke also of the embossments, and of the cast works of those nations, so far removed both in point of time and locality."—*Kohl's England*.

Let me recapitulate, so as to impress upon your minds the treatment in acute cases; and I would here notice a fact of great practical importance, which is, that the case may be acute and yet, in consequence of the agonizing pain endured by the patient and his loss of rest, the evidence of constitutional power as evinced by the pulse, even in a man habitually vigorous, may be entirely absent; the pulse in such cases being quick and weak. This must not deter you from depletion, or induce you to administer quinine or other tonics; for if you do, the inflammation and its results will be certainly aggravated. Well, then, you bleed "*pleno rivo*" as the physicians of old used to write, but not "*ad deliquium animi*;" confine the patient to his bed; lightly bandage both eyes with a fine soft linen roller, keeping the affected organ cool by the frequent application of a belladonna lotion rendered slightly evaporative by the addition of spirits of wine; enjoin a spare, unstimulating, and fluid diet; administer calomel and opium; deplete from the temple, as the objective symptoms may indicate; at a later period use a repetition of flying blisters to the same part. The low diet must not to be continued too long, or the reparative power will be unequal to the filling up of the breach in the cornea. As soon as we detect a decidedly mercurial fetor of the breath, we administer the medicine at longer intervals, and allow some weak animal broth, gradually increasing the strength of the latter if it prove salutary. Opiates must be given at bed-time to procure sound sleep; of these, Dover's powder in from twelve to twenty-grain doses, is in my opinion, preferable; it acts upon the skin, and promotes the action of the mercury.

If the pain in the eye be very severe, it will be radiated to the forehead and side of the head, (hemicrania,) to the cheek bone and nose, following, you perceive, the distribution of some of the ophthalmic branches of the fifth pair of nerves. It may become intolerable, in which case, supposing we are satisfied that it has its origin in the distended cornea,* we are justified in puncturing the abscess (onyx) with a Beer's cataract knife. The matter will not flow out as in an ordinary abscess, but gradually bulge little by little from the opening, so lymph-like is its consistence. When the abscess has been opened by the knife, and even when not so interfered with and treated with all the care I have indicated to you, instead of absorbing, it may ulcerate or slough, the lamellæ forming the posterior wall of the abscess rupture, and the iris is projected through it (*staphyloma iridis*), laying the foundation, if the wound be large, of a staphyloma corneæ. If the protruded portion be small, it will ulcerate to a level with the cornea, and remain adherent to the cicatrix. This is synechia anterior. The perforation of the cornea by ulceration, and escape of aqueous humour, is, on the other hand, in some cases, a favourable event, being the immediate precedent of subsidence of ophthalmia; the humour is regenerated, the iris recovers its normal position, or becomes merely adherent at the point of perforation. The patient's vision would be

perfect, if we could dissipate the leucoma from the axis of vision. The mere contact of the iris with the inner concave surface of the cornea does not endanger the integral dimensions of the anterior chamber. There must be an exudation of lymph, as well as contact, before adhesion can be effected; if it were not so, the removal of cataract by extraction, in which operation the aqueous humour is invariably lost, would be nearly always fatal to vision. I saw a man, a short time since, who had, the day before he came to me, received a small incised wound near the centre of the cornea, which had penetrated the anterior chamber; the wound was closed, the iris had been floated back to its natural position, having spun, as it were, a fine thread of lymph in its passage from the cornea.

In Case 2 (Ballard) the normal configuration of the cornea was said to have been restored in the course of two hours after the escape of the humour, so rapidly is the aqueous humour secreted. The new material supplied for the repair of a loss of corneal substance, is at first of a greyish colour, translucent, not transparent, becoming as it consolidates more opaque. When reparation is going on in the centre of the cornea, we often notice a red spot or streak in the middle of the exuded matter, indicating the development of new vessels for the completion of its organization. In other instances, more particularly if the injury be near the margin of the cornea, a number of little vessels are projected from the conjunctiva and sclerotica into the cytotblast; the vessels, in either position, fade away upon the completion of cicatrization. In some few cases one or more vessels are required for the maintenance of life in the new tissue, and these are permanent. This outline of the reparative process in the cornea is at once suggestive of a rational treatment; namely, to support constitutional power by a nutritious and easily digestible diet; allowing a certain amount of whatever alcoholic stimulant the patient may have habitually taken, when in health. At this period we must be careful how we apply leeches, even though pain be present, which is generally of a neuralgic character, or we shall so interrupt the formation of the new material as to favour the production of staphyloma, or induce so rapid an absorption of the exuded matter that the cornea will give way under pressure of the contents of the globe, and the anterior chamber, drained of its secretion, will be collapsed. As a local application, the belladonna collyrium is one of the most useful, and very agreeable to the patient. Much harm is done by the indiscriminate application of astringents, such as zinc and nitrate of silver, to every species of external ophthalmia. When the lymph lies or hangs loosely upon the wound, the introduction of two or three drops of a solution of nitrate of silver, (gr. ij. or gr. iv. to the ounce of water,) within the lids, or directly to the part by means of a camel's-hair pencil, will tend to consolidate the wound. The drops are to be applied once or twice in the twenty-four hours. If from any cause there should be an exacerbation of inflammation, and we determine to apply leeches, they should be placed over the mastoid process, in preference to the temple. Before

* The cornea is highly endowed with sensitive nerves.

concluding these remarks, I must again remind you that abscess of the cornea, as a result of the impaction of a foreign body, seldom presents itself in a person of sound constitution, therefore venesection is rarely demanded. Do not go away with the idea that because you have a patient affected with abscess he must necessarily be bled. If you have any misgivings of the propriety of general bleeding, adopt local depletion.

Abscess of the cornea is frequently complicated with the presence of purulent matter in the anterior chamber (hypopion); in fact, the former occasionally discharges itself into the anterior chamber. A difference of opinion exists among ophthalmic practitioners as to the propriety of puncturing a corneal abscess. The operation is advocated by Dr. Jacob, of Dublin, on the principle that wherever pus is collected, it should be let out. Mr. Guthrie considers treatment by *incision*, not by puncture, to be the most successful method of curing the disease under consideration. Other authorities, including my late preceptor, Mr. Lawrence, Dr. Mackenzie, and Mr. Tyrrel, condemn the practice, because they have found that the pus corpuscles are capable of removal by treatment very similar to that I have suggested for your guidance at the commencement of this lecture. Dr. Mackenzie has observed staphylococci more frequently after puncture than when it has been dispensed with. Mr. Guthrie, in one of his clinical lectures, reported in the *Medical Times*, says, "I wish you to recollect that the operation I recommend in these cases, (abscess of the cornea and its concomitants,) is not a puncture; it is a division of the cornea, made (perpendicularly through it) by the best cataract knife you have, beginning immediately below the edge of the interstitial abscess, and extending to a similar point above it, the internal opening in the cornea being, as nearly as possible, as large as the external one. The whole of the aqueous humour, and other matters, should be suddenly discharged, when the iris falls or is pressed forward against the cornea. Care must be taken not to injure the capsule of the lens." "If the whole of the aqueous humour should not have been let out, together with the matter constituting the hypopion, the edges of the wound in the cornea must be separated by the curette." We are also directed to keep the eyelids, after the operation, closed, and covered with a soft pad of linen, maintaining by the bandaging a moderate degree of pressure for twenty-four hours; the eyelids are now to be cleansed, but not opened, for forty-eight hours; when, Mr. Guthrie says, in some instances, the edges of the incision will be found to have united, and the anterior chamber to be full of aqueous humour; the ulcerated part in a healthy state, and all the other symptoms greatly relieved. In the *Medical Times* for October, 1843, and February, 1844, you will find some cases recorded, which were treated by incision. I have often punctured the cornea, but never incised it in the way recommended by Guthrie; the patient has generally obtained temporary relief from the painful sense of distention which is present in this disease. In my next lecture I shall have to advert to some cases which were so treated.

Hospital Reports.

BRISTOL ROYAL INFIRMARY.

CASES

Reported under the Terms proposed by the Association.

BY NIL DESPERANDUM.

Strangulated Scrotal Hernia.

THOMAS KNIGHT, aged 38, was admitted March 31st, 1851, under the care of Mr. Clarke, for strangulated scrotal hernia on the left side. He states that he has had a fulness on that side for the last eighteen years, but it had never given him any inconvenience, although it became somewhat larger on any violent exertion. Six days ago it became much larger after exerting himself more than usual, and which was followed by vomiting and hiccough. He had assistance on that day, but the surgeon could not reduce the hernia. On the following day his bowels were moved, but the vomiting was not relieved. The symptoms continued for the next four days without any alteration, except an abatement in the vomiting. During this time has had no tenderness in the tumour.

Present symptoms.—A tumour about five inches long, not tense; pulse 72, small; tongue covered with a brown fur. The surgeon who attended him states that his bowels were opened this morning after the administration of an enema. On consultation, Mr. Clark determined to wait until the evening, as there seemed no immediate necessity for operating. Ordered the application of ice to the tumour for an hour, and an enema of gruel as well as a draught, with Liq. Opii Sed., m. xl.

Eight o'clock p.m.—His bowels not having been moved, Mr. Clark operated at once. Having opened the sac, a large quantity of omentum came into view with a coil of intestine between its layers. The stricture was easily divided, and the intestine (which was tense) returned into the abdomen; it was deemed advisable not to remove or to attempt to return the omentum into the abdomen. The wound was brought together with three sutures, adhesive plaster, and bandage. There was scarcely any bleeding, and he did not complain of any pain, as he was fully under the influence of opium.

April 1st.—Feels very comfortable; slept tolerably well; no nausea or sickness. Has taken beef-tea with relish. Rather more secondary hæmorrhage than there should be. Scrotum and prepuce much swollen but not painful, the swelling of the latter causing paraphymosis and retention of urine. Paraphymosis reduced and catheter passed.

April 2nd.—Slept but very little last night. Scrotum rather painful, tense and ecchymosed. Has had no motion, but is constantly passing gas, and a slimy kind of mucus; no tenderness of abdomen; excessive thirst;

pulse 112, weak; sutures removed; the wound filled with a coagulum. An evaporating spirit lotion to be applied to the scrotum. Soda water *ad libitum*.

Ten o'clock P.M.—Very restless; thirst continues; bowels have been moved five times.—*R. Tinct. Opii, dr. ss., Aq. oz. j. Fiat haust statim sumendus.*

3rd.—Feels much better; has slept well; scrotum and prepuce of a purple colour; thirst continues; skin hot; pulse 128; bowels opened twice; no tenderness of abdomen; passes water freely. Poultice to scrotum. Ordered an ounce of port-wine every hour. Beef-tea, arrowroot, and eggs.

4th.—Has slept well; pulse 120; tongue dry and coated; scrotum not so tense; but looks dark, as though about to slough. There is a constant exudation of dark venous blood from the wound. The original incision continued downwards for two inches, and turpentine applied to the surface. To have six ounces of wine daily.

5th.—No hæmorrhage; seems better; appetite good; tongue moister; considerable sloughing at the lower part of the scrotum. There is an exudation of sanguineous serum from the wound.

6th.—Much better; pulse 108, stronger; tongue moist and cleaner; appetite good; wound sloughy; dressed with Unguentum Resinæ c. Terebinth. under the poultice.

14th.—Has continued to improve. Slough has separated, and the surface is granulating. To omit the poultice, but to continue with the Ung. Res. c. Tereb. Appetite good; bowels regular. To have four ounces of wine and one quart of beer daily.

Under the influence of a good diet and stimulating applications the wound quickly healed, considering the large amount of sloughing, and he was discharged, perfectly well, on May 10th.

The chief points of interest in this case are,—1st., the treatment at the operation in respect to the large mass of omentum—viz., not either attempting the return of it into the abdomen, where it might act as a foreign body, or of removing it, which would have given rise most likely to a great deal of hæmorrhage, (not at the time of its removal, but secondarily as the case turned out,) and would have required many ligatures; 2ndly, the sloughing and secondary hæmorrhage after the operation. Both of these consequences are to be ascribed to the excessive sedative and depressing effects exercised on the parts locally by the application of the ice. It is probable that some little time after the operation, when the parts had recovered from the astringent action of the ice, and reaction had come on, blood was poured out rather freely into the scrotum; and this might have also aided in producing the sloughing of the scrotum, secondary of course, as compared to the ice. In this case, the excessive sedative effects of the ice, no one could have foreseen or guarded against, as its application was of short duration. It is a disadvantage in the employment of ice, that you are not able to controul its effects and thus prevent the awkward complications that occurred in this case.

Strangulated Inguinal Hernia.

THOMAS TANNER, aged 65, was admitted August 18th, 1851, under the care of Mr. Harrison, with apparently strangulated inguinal hernia on the left side; symptoms denoting strangulation in its acutest form were wanting. The taxis was employed and the intestine was felt to go back; but a swelling still remained, which, from its doughy feel, was evidently omentum. A compress and bandage were applied at the ring.

On the 19th he still had symptoms of great uneasiness and some abdominal tenderness. On the following morning Mr. Harrison was sent for on account of his great depression and the abdominal tenderness having increased. Although the tumour still felt as only omentum, on consultation, Mr. H. determined on operating, as affording the patient the only chance. Brandy was freely given before the operation. There was a cicatrix in the direction of the inguinal canal, as if he had undergone some operation previously; the man did not corroborate the opinion, but from having a great defect in his speech, it was impossible to obtain any accurate account of his previous history. On opening the sac, nothing but omentum was present, which looked congested, and was adherent to the sac. As the man was so much depressed, and Mr. H. felt convinced that there was no intestine or omentum strangulated, he was removed to his bed. The typhoid symptoms continued, and he had an attack of diarrhoea which exhausted him very much, and he died six hours after the operation.

Sectio-cadaveris.—On opening the body, serous effusion was found in the abdominal cavity, with peritonitis. The intestines generally were much congested, giving the appearance of acute enteritis. On examining the seat of operation, no intestine was found down or in any way strangulated. The commencement of the rectum was adherent to the peritoneum lining the abdominal parietes at a point external to the internal abdominal ring, but this evidently was not of recent date, and the passage of the gut was in no way affected. On tracing the rectum farther down, within three inches and a half of its termination, there was a spot of pus at this part, and on taking out this part of the canal, and slitting it open, the mucous membrane was found excessively congested, (almost amounting to inflammation,) in the form of irregular patches. The rectum, in its whole extent, was thicker and more tumefied than normal.

Strangulated Scrotal Hernia; Rupture of the Intestine; successfully treated by Operation.

WILLIAM MANNING, aged 24, admitted December 22nd, 1850, under Mr. Clark, for strangulated scrotal hernia on the right side. He is a stone sawyer, in regular work, unmarried. He states that his habits are regular and sober, and has been ruptured for about twelve months, but has always been able to return the rupture till within the last nine days. He informs me that the hernia came down on December 13th, while at

work, (he had been lifting some heavy pieces of stone the day before,) and that he got back a portion of it at the time, but was not able to return it altogether. A short time after the descent, he suffered so much pain that he was obliged to go home and go to bed. He was attacked with vomiting on the following day, which has continued more or less till within the last two days. Had hiccough severely on the 16th, 17th, and 18th of December. On the 19th he walked to a surgeon's residence, but he was not examined by some unaccountable circumstance or other. The above surgeon saw him to day, and tried to reduce the tumour, after bleeding him to about sixteen ounces, but the attempt did not succeed; he then placed him under the influence of chloroform and tried the taxis again, but failed. The man was then brought to the Infirmary. On examination there was found a tumour on the right side, about four inches in length, and of pear-shaped form; it was not tense, and bore a moderate degree of handling without the man complaining of pain. His countenance looks anxious; tongue brown, dry, and furred; skin clammy; abdomen tender; pulse slow and weak, 84; bowels have not been moved for the last nine days. The taxis was gently tried, but on account of the vomiting, hiccough, and all the other symptoms of strangulation having existed so long, was not persevered in.

Operation at twenty minutes past eight P.M.—There seemed to be an unusual thickness of structures, and a great many layers were divided. On opening the sac, a rather large quantity of fluid escaped; the intestine was red and looked rough; it was adherent around the whole circumference of the neck of the sac. While Mr. Clark was feeling to see whether there was a communication with the abdominal cavity, the intestine gave way. On a closer examination, the intestine was found emphysematous, although it did not look dark. It afterwards gave way in two other places, and a large quantity of liquid fecal matter escaped. Mr. Clark then opened the intestine for about three inches, and gave free exit to the contents; a piece of lint dipped in tepid water was then applied to the exposed intestine, and he was removed to his bed. His pulse had risen to 120 during the operation; it was weak. He took an ounce of brandy just before the operation.

Ten o'clock, P.M.—A large quantity of fecal matter has passed through the wound. Pulse small, 130. Ordered the following mixture:—R Liq. Opii Sed., dr. j.; Aq., oz. vj. Capt. oz. j. quartis horis. To have middle diet and arrowroot.

23rd.—Nine o'clock, A.M.—Feels easy; a large quantity of fluid passed through the wound. Has dosed a little during the night; pulse firmer, 112; tongue furred and dry.

Four o'clock, P.M.—Much the same; pulse 120.

Half-past nine, P.M.—Complains of pain over the bowels; pulse 130. Ordered milk to drink.

24th.—The pain over the bowels but very slight; skin not so clammy; tongue cleaner and moister. Capt. Mist. oct. horis.

25th.—Feels quite easy; free discharge of liquid fecal matter through the wound. Pulse soft, 80

December 26th.—Free discharge from wound; passed two motions per anum last night. Pulse 72. Capt. Mist. omni nocte. Ordered beef-tea.

27th.—Motions passed per wound. Pulse 72; tongue clean; appetite pretty good.

30th.—Two bed-sores on the sacrum and one on the hip, were discovered to day. Ordered the following application for them:—R. Cretae, dr. iv.; Zinci Oxidi, dr. ij., fiat unguentum. To have a chop daily at eleven and full diet.

21st.—Feels a little pain about the wound; undigestible matter, in small lumps, passed through the wound.

January 1, 1851.—A large quantity of dark offensive matter passed through the wound; very little pain; appetite good.

4th.—He takes his food with great relish, and always feels ready for his meals; sleeps well; pulse 72.

10th.—A large and hard motion passed last night per anum. He says that at the time, the intestine almost disappeared through the wound; the intestine has somewhat receded the last four or five days. Pulse 72, soft. Bed-sores healed.

11th.—Complains of the intestine and surrounding parts being painful since the last motion per anum. Fæces pass through the wound to day.

17th.—The pain is gone. Excepting this no alteration since the last report.

24th.—Feels quite well in himself, and has quite a ravenous appetite. The intestine appears sometimes to be smaller, and at others larger. The fæces pass through the wound.

February 3rd.—The fecal matter, which is liquid, escapes entirely through the wound. Gaining flesh. Appetite good. The textures between the integument and intestine, (which were noticed at the time of the operation to be unusually thick,) are much lessened.

10th.—The textures surrounding the intestine seem to be entirely absorbed; and the intestine has receded. If he eats potatoes they pass through the wound undigested.

February 16th.—The portion of mucous surface of the intestine at the wound is smaller, measures about two inches and a half; there is a little portion of the mucous membrane adherent to the skin at the upper and external margin of the wound. General health good.

22nd.—Mr. Clark introduced a finger into the opening of the lower portion of the intestinal canal, (which opening is small and situated at the upper part of the wound,) and another finger into the opening of the upper part of the canal, (which opening is large, everted, and situated at the lower part of the wound,) and found that the two portions of intestine lay parallel, and in almost close contact as far as his fingers could reach; the lower portion of the canal makes a curve downwards to the upper.

28th.—A tape-worm presenting to day at the opening of the upper portion of the canal, I tried to extract it, but it broke off before the whole worm was extracted;

the portion measured thirty-two inches. He has passed several small worms during the last three or four days. Fæces pass entirely through the wound. Health good. He continued in this condition, without anything of note occurring, till

March 17th.—The remaining portion of the tape-worm, measuring forty inches, came away through the wound this morning. Local condition the same.

21st.—Mr. Clark introduced a pair of Dupuytren's forceps to-day, for the purpose of making a communication between the upper and lower portions of the intestine. After the blades were screwed tightly together he complained of pain in the bowels, and fell sick. Ordered—R. Liq. Opii Sed., m. xxx.; Aquam, ad. oz. iss. Fiat haust statim sumendus. To have middle diet, milk, and arrowroot.

Forty-five minutes past eight, p.m.—Not in much pain, but countenance looks anxious; has vomited twice. Has not slept, although he took the opiate five hours ago.

22nd.—Did not sleep last night; vomiting ceased; no tenderness, but complains of slight pain in the bowels. The exposed intestine has somewhat receded within the wound. Pulse 84, soft. Tongue slightly furred.

24th.—Rather puffy and painful around the intestine to-day. The quantity of fæcal matter passed by the wound has somewhat diminished the last day or so. Pulse 84; tongue clean. The forceps were screwed up to their full extent.

26th.—The swelling around the intestine has subsided. Has had a great quantity of gas escape from the rectum since yesterday. No fæcal matter passed by the wound since this morning. Pulse 72; tongue clean.

27th.—Has not passed any flatus by the rectum to-day; nor is there any fæcal matter passed by the wound.

28th.—Has had nothing pass through the wound except a little watery fluid, which appears to be secreted by the mucous membrane of the exposed intestine.

29th.—Has had a little fæcal matter pass by the wound to-day.

30th.—At the operation (original), when the incision into the intestine was made, it was considerably on the side of the mesenteric surface of the intestine, consequently, when the intestine threw itself open there would be two portions of mucous surface at the wound. This larger portion, which is superior, looks prominent to-day, and the base, where it is continuous with the portion included between the forceps, looks dark and sloughy. There was a considerable discharge of dark-looking fluid from the wound this morning. The forceps have sunk to the lower part of the wound, evidently showing that the portions of parallel intestine have inflamed and united, and that the portion of the intestine included between the forceps is in process of separating. General health very good.

31st.—Mr. Clark, thinking that there was now a communication between the upper and lower portions of the canal, ordered an enema to be administered; while the man was turning round the forceps dropped

out of the wound. The injection returned immediately after it was given. On examining the rectum it was found quite blocked up by hardened fæces; these being removed by means of a lithotomy scoop, the following injection was thrown up:—R. Spt. Tereb., dr. ij; Olei Ricini, dr. iv.; Dec. Avenæ, oj. This also failed in unloading the bowels. The man himself stated that new beer purged him generally. He was ordered half a pint. One hour afterwards a motion came away. It was not hard, but of a peculiar whitish clay colour; perhaps this may have resulted from a mixing with the secretion of the lower part of the canal. There is a slight discharge through the wound.

April 3rd.—Has had no motion per anum since the last report. No discharge from the wound. To have a chop daily.

5th.—Has had a slight discharge of fæcal matter through the wound since the last report. On introducing a finger you find the communication between the two portions of the intestine, about one inch and a half from the external wound; you can also feel a kind of band, where the two portions of intestine are amalgamated. On either side of the septum your fingers enter the cavity of the two portions. The part of mucous membrane (external) is rather more prominent. Has had no motion per anum yet.

7th.—Passed a motion per anum last night, not large, but of good colour, &c. A discharge of yellowish matter from the wound to-day, partly fæculent.

9th.—Has had two very hard and small motions per anum since the last report, which caused him to strain so much that there was a slight discharge of blood with them. A little fæcal matter comes through the wound.

11th.—He was ordered the following injection for this morning:—R. Extr. Fel. Bovis, oz. j.; Dec. Avenæ, oj. This brought a larger motion than usual. Very little discharge through the wound.

14th.—He had another injection of ox-gall yesterday, and one this morning. The injection yesterday brought away a very large quantity of fæcal matter; that is the first time since he underwent the operation for hernia, (nearly four months ago,) that he has had a large motion per anum. A truss, with a weak spring, was applied to the wound yesterday.

17th.—The truss does not make pressure on the prominent piece of mucous membrane, but on the side of the wound, which has caused a swelling of the integuments, and given him pain. Had an injection this morning, which brought away a large motion. There is a slight discharge of mucus-like fluid from the wound, but there is no fæcal matter with it, nor has there been any for the last week.

19th.—The truss was removed to-day, and several compresses of lint, with a square piece of board over these, were applied over the wound, and kept down by means of an elastic India-rubber band. Has had no motion per anum since the last report; his bowels do not yet act without an injection; no alteration in the discharge.

20th.—Had his bowels freely opened this morning

without any injection; the motion was large, of good colour, &c. The compress, &c., does not pain him, and keeps up very effectual pressure.

23rd.—His bowels have acted regularly every day per anum since the last report; he does not require the enema; the wound has closed a little lately, and the portion of intestine that was so prominent, has receded within the wound since the effective pressure with the compress; there is a little mucous discharge from the wound.

27th.—The elastic band broke two days ago, since then the compress has been kept down with bandage; the lips of the wound have been drawn together with adhesive plaster; there is not so much of the intestine appearing externally, neither is there so much mucous discharge from it; bowels act regularly every day.

30th.—I found, on examining the wound to-day, that a little faecal matter was escaping, and it appears that a very little faecal matter has escaped through the wound for the last two or three days, after he has taken his dinner; bowels act every day; condition of the wound the same.

May 8th.—The wound is a little smaller, but there is still a little discharge from it. In a former report it was stated that the portion of intestine at the wound was adherent to the skin. Mr. Clark applied potassa fusa to it, and then strips of Emp. Adhesiv. Comp., &c.

12th.—The skin around the wound is sore, from the application of the potassa fusa; it was applied again.

16th.—No union of the wound having taken place, and the margins being in a favourable condition, Mr. Clark brought the wound, (which is about two inches long,) accurately together, by means of two sutures, and Emp. Adhesiv.

17th.—The wound was quite open this morning, from the sutures having cut through the skin; the integument around the wound was somewhat inflamed before the sutures were used. Strips of Emp. Adhesiv. were again applied.

22nd.—Wound is getting smaller, still a little discharge from it after his dinner; bowels act regularly. A compress of lint was placed on the wound to-day, and confined by means of Emp. Adhesiv., &c.

28th.—The wound is closing a little. From the application of the potassa fusa one margin of the wound is free, but the other is adherent to the intestine. Mr. Clark applied it again to the margin that is adherent.

June 4th.—Wound much the same. Potassa fusa again applied. Bowels act regularly per anum.

10th.—The potassa fusa has caused a slight slough of the skin around the wound where it was applied. After his dinner, if the compress is removed, a rather large quantity of faecal matter (liquid) will pass through the wound. Ordered not to eat potatoes.

16th.—Nothing like so much faecal matter passes through the wound since his diet has been confined to meat and bread. The skin around the wound has been somewhat sore and inflamed for the last week, from the irritation caused by the escape of faecal matter. Has had no motion per anum for three days. Ordered—Pil. Hyd. Laxantes, iij., statim. The following dusting

powder has been applied to the wound and surrounding parts for the last five days:—R. Zinci Oxydi, dr. iij.; Cretae, dr. iv. M.

22nd.—The wound is better, and the surrounding parts are not so inflamed since using the dusting powder. His bowels act freely and regularly.

27th.—The man was placed under the influence of chloroform, and Mr. Clarke enlarged the wound at its upper angle, and then pared the edges completely. He then introduced five pins, and passed a thread round each in the same way as in the operation for hare-lip. Strips of adhesive plaster were used, and a compress. He is not to take more food than is absolutely necessary.

30th.—There is a slight discharge—perhaps pus mixed with the secretion of the intestine—from the lower angle of the wound. Bowels not moved since the operation.

July 1st.—On removing the strapping to-day, found that the last pin at the lower angle of the wound had ulcerated through, and there was some discharge of faecal matter from that part. Mr. Clark removed the other pins, and found that the greater part was in apposition. Adhesive plaster applied; bowels not yet moved. Ordered a turpentine enema.

2nd.—The wound was again dressed to day, and it was found that for the whole extent, with the exception of a small portion at the lower angle, it had united. Bowels have not been moved. To have an ox-gall enema.

4th.—There was some discharge of faecal matter with pus from the wound to day; the discharge seems to come through in those places where the pins were introduced. The wound appears united in the interspaces. Bowels have been opened freely. Dressed with Emp. Adhesiv. Comp.

7th.—The wound is much improved since the compress was applied. A little faecal matter from three small openings, where the pins were extracted. Bowels regular.

10th.—The three openings are smaller, and there is but very little discharge from them. The remainder of the original wound is perfectly adherent. Bowels act well.

14th.—One of the openings is closed; there is only some discharge from two of the openings.

19th.—To day there is only a little discharge from one opening, the other has closed since the last report.

24th.—There is no discharge to day although the opening has not closed. His health is very good.

29th.—From his having exerted himself, there was a slight discharge from the now very small opening; the integuments round the original incision looked puffy, as if he had received a blow, which he says he has not.

August 1st.—The swelling has subsided, but the opening still remains. It being suspected that he had worms, Mr. Clark ordered him a dose of the koussou, which brought away several small portions of a tape-worm. The head was found in the portions passed.

4th.—There is no discharge from the opening, which is closing.

9th.—A little faecal matter came through the open-

ing to-day; the opening is about the size of a pin's head.

12th.—There has been no discharge since the last date; cannot see the opening to-day. The dusting powder is still applied with the compress. Bowels regular.

18th.—The opening has entirely closed, and there has been no discharge for the last nine days. After his dinner the integument at the part bulges out, evidently from the pressure of the faecal matter from within. Bowels act regularly.

29th.—Remains perfectly well. Has been allowed to get up for the last week. He is to remain as an in-patient for some time longer, to see that there is no disposition to the re-formation of a fistulous opening.

He left the Infirmary in the latter part of September, perfectly well, without any symptoms that would indicate that he would be likely to suffer from any bowel obstruction. He was directed to wear a square piece of padded deal, to be kept on with a truss with a weak spring. Nearly five months have elapsed since his dismissal, and I believe he remains perfectly well.

Remarks.—This is one of those cases that illustrate the efficiency and power of surgery in completely relieving an individual from a most disgusting infirmity, resulting from strangulated hernia going on unchecked. The successful treatment of this case bears out the opinion that is held concerning the time that Dupuytren's operation should be attempted, viz.,—"in allowing sufficient time to elapse for the irritability and sensibility of the gut and septum to be lessened by the influence of the external air and the pressure of the faeces." The comparatively slight symptoms, and their short duration after the introduction of the forceps, show that the parts did not possess those properties that we usually associate with structures so highly endowed with vessels and nerves as the intestines are. It was quite clear that nature was not equal to a partial much less even a perfect cure in this case, the difficulty arising from the very acute angle formed between the two portions of the gut. After the forceps came away, great difficulty was experienced in getting the bowels to act, the rectum being quite blocked up with hardened faeces, so as to require manual interference, besides the repeated exhibition of enemata. The administration afterwards of the ox-gall seemed to exercise a very beneficial effect, as stimulating the muscular coat of the intestines, after such a long period of inactivity. The performance of Dupuytren's operation was not sufficient for the perfect cure of this case. In some cases that occurred to Dupuytren, however, a perfect cure followed this mode of procedure, the wound gradually contracting, and after a time entirely closing. From the tendency to what, I suppose, may be called prolapsus of the mucous coat of the gut at the wound, it was necessary to make pressure on it, which was made with good effect. The application of chalk and oxide of zinc to the integuments around the artificial anus was a palliative measure that afforded great comfort to the patient, thus preventing the

excoriation of the skin that would have necessarily ensued from the contact with the faecal matter that was constantly escaping. On account of this matter, to a small extent, continuing to pass through the wound, and that in a fluid state, it was evident that a perfect cure could not be effected, unless this could be almost, if not quite, prevented. With this view his diet was confined to meat and bread; and then the plastic operation was performed, viz.,—that of paring the edges of the wound, and bringing them accurately together with pins and sutures. As the report of this case states, the fistulous openings made by the insertion of the pins did not entirely close for more than a month. It has occurred to me whether the formation of these small fistulous openings may not be avoided by only partially transfixing the entire thickness of the structures. Previous to this the margins of the wound, having been made sore by the application of potassa fusa, were brought together by interrupted sutures, but it did not succeed; and I think that it may be a question whether in cases which require additional treatment after the performance of Dupuytren's operation, it would be better to have recourse to the former proceeding, as being the more certain of the two. Of course this very interesting case might have called forth many remarks, but I thought that it would be better to confine them to the most prominent points.

Provincial Medical & Surgical Journal.

WEDNESDAY, MAY 12, 1852.

WE think it better to reprint at length the Draft Bill of Medical Reform, as amended by the Central Council, because the alterations are of such a nature as to require the whole of the clauses to be placed at once before the reader, in order to understand them. The following are the chief points in which the amended Bill differs from that printed in a former number:—1st. In the appointment of the Medical Council, the Secretary of State is substituted for the Apothecaries' Company. This alteration has been very generally suggested, and is, we think, a great improvement; for though it may, perhaps, entail upon us some increase of opposition from the Apothecaries' Company, still we had no reason to suppose that they were very friendly to the old measure, but rather that they would oppose it as far as lay in their power. The succeeding Clauses, up to 12, which define the machinery for working the several Councils, are, with mere verbal alterations, the same; as is also the 13th, which provides for the registration of existing practitioners; but in the 14th, 15th, 16th, 17th,

and 18th Clauses, which are those relating to the examination and registration of *all future medical practitioners* by the Medical Councils, a very considerable alteration will be found to have been made. It is now proposed that every one, after the passing of the Bill, who intends to practise medicine or surgery, shall present himself before the Council of the country in which he is about to practise, having certain testimonials in his possession to prove the nature and extent of his education; then that the said Council shall examine him as to his fitness to practise medicine, surgery, midwifery, and pharmacy, and, upon being satisfied as to such fitness, shall grant him a licence to practise under the name of a Licentiate of Medicine.

But before taking advantage of this licence, it is provided by the 26th Clause, that the Licentiate shall be registered, and the mode of so doing is laid down by the 17th Clause, which enacts that he may be enrolled in the books to be kept for that purpose, on the production of his licence, together with the diploma or licence of the Royal College of Physicians or the Royal College of Surgeons, of the country in which he intends to practise. So that in future all medical practitioners would come to be classed and registered as physicians or surgeons; though the latter might, and most probably would, as at present, be subdivided into those who practise surgery alone, and those who add to it the practice of midwifery or pharmacy, or both. The remaining Clauses are only slightly altered, with the exception of the 22nd and 34th, which are altogether omitted, as being unnecessary under the altered conditions of the Bill.

The proposed alterations, it will be easily perceived, will simplify the Bill very materially, and we think will also considerably add to its efficacy in practice; for since we are compelled to make use of the materials already existing, in the shape of the Colleges of Physicians and Surgeons, it is surely desirable to make the best use we can of them, and this we think is done by the amended Bill. The total omission of the term "apothecary" is also a great improvement, since it is disliked and repudiated by all; and we can see no objection to the proposed legalization of the present popular name of "surgeon."

In future all must pass through one common portal—the examination of the Medical Council, but in addition, they must attach themselves either to the College of Physicians or to the

College of Surgeons, and under their new Charters we hope and trust that all will be cordially received and fairly represented. We do not say that those bodies will be faultless in their composition, but still the grievances to be complained of are so trifling, that we think they will not, in actual working, interfere with the well-being of the whole body.

Such, then, is the present aspect of the proposed scheme, which we sincerely believe will be carried out in the next session of Parliament, if the Provincial Medical and Surgical Association should generally accord their approbation to it at the ensuing meeting at Oxford. It has been no easy task to construct it, and scarcely less so to alter it in accordance with the suggestions of the numerous parties who have taken an interest in it. There will, no doubt, still be a very formidable opposition to meet from the existing institutions, but we are assured that that opposition *may* be overcome, and that it only requires "a long pull, a strong pull, and a pull altogether," on the part of the profession, to overcome all obstacles, and settle the question of Medical Reform on a basis satisfactory to all men who are not wilfully and unnecessarily querulous.

Reviews.

The Journal of Psychological Medicine and Mental Pathology. Edited by FORBES WINSLOW, M.D.
No. 18, April, 1852.

At the time this periodical work first made its appearance, we were sceptical as to the support it would receive from the profession, having a knowledge of the comparatively small amount of personal interest which was felt on the subject of insanity, arising from the fact that its treatment was generally confided to a small and special section of medical practitioners. Dr. Winslow has, however, by the force of his own genius and perseverance, shown us that, great as the apparent difficulties were to the establishment of a journal exclusively devoted to psychology, they were not insurmountable; and we believe we may now congratulate him upon having achieved an amount of success, at least satisfactory, if not commensurate with his deserts. It must, we think, be generally admitted, that not only the profession, but the public in general, are deeply indebted to Dr. Winslow for this, his

able endeavour to surround the diseases of the mind, with all the literary appliances of science, and to place their study in that prominent position, which is their undisputed due; and we are but doing him bare justice in stating our conviction that his excellent journal should be possessed and read by every one who is interested in the moral welfare of his species, whether as physician, statesman, or friend.

The "*Journal of Psychological Medicine*" has now been upwards of four years in existence, and its eighteenth number is now before us, and like its predecessors contains several articles of great interest, among which we may enumerate one "On Crime, Education, and Insanity," on the "Psychology of Epochs," on "Nervous Influence," &c. This number also contains a detailed and authentic account of the famous case of Mrs. Cumming—a case which should be carefully studied by every one engaged in lunacy practice.

As a specimen of the literary workmanship of this journal, we will quote a passage from the first article, in which the writer enforces the difficulty of defining "irrationality," and therein alludes to the case already mentioned.

"It is for this reason that the facts which are commonly presented to medical witnesses, as a criterion to test the sanity of a party are often absurdly equivocal. In the recent inquiry into Mrs. Cumming's case, the attention bestowed on half a dozen cats was gravely tendered as a proof of irrationality, as if every old woman in the country had not half a dozen pets of one kind or other at her elbow. In other cases slovenliness of dress, jealousy of female attendants, apprehension of domestic treachery, and even eternal scribbling, have been quoted as evidences of an aberrated reason, sufficient to satisfy a physician who is to guide a jury. If the question were whether these feelings were inconsistent with a well-regulated mind, that is, a mind governing its will by certain fixed utilitarian principles, such facts would be relevant to the issue; nor can it be denied that an accumulation of habits decidedly eccentric and motiveless, warrants a suspicion of derangement; though even in that case, it is only suspicion in aid of proof. No single fact, nor accumulation of facts, for each of which a possible, though inadequate reason may be assigned, is, *per se*, conclusive of irrationality; as for instance, had it been proved that Mrs. Cumming was in the habit of walking backwards in the park for half an hour daily, what stress would have been laid on that peculiarity! Yet no man can take a pedestrian tour through Wales, without occasionally witnessing a similar exhibition, in well-

dressed, sensible-looking young gentlemen; it being well known to all addicted to such amusements, that the intercostal muscles are greatly relieved, especially in ascending hills, by a change to backward walking. Apprehension of domestic treachery is always a favourite topic with pro-lunacy counsel; yet one of the most eminent artists of the day, whose intellect is as brilliant as his colours, for many years pursued the habit, and perhaps pursues it still, dictated by similar distrust, of baking his own bread, grinding his own flour, and dressing his own dinner, with the same hands which gave animation to his canvass. A single act may be *ultra* the restraint of reason; even an habitual practice may be motiveless to absurdity, and to that extent irrational, and yet common sense forbids us to regard it as insanity. Nebuchadnezzar, on being restored to understanding, might have retained in his palace some of the freedoms of his seven years apprenticeship to brutality; he may still have found dress an incumbrance, ablution a painful nuisance, and all the restraints that decency imposes on social intercourse, for a time unnatural. * * He might have plausibly urged that a sudden change to the warmth of clothing would be prejudicial to his bodily health; that frequent washing was painful to the new cuticle; that the peristaltic action, would be impeded by needless control. Such reasoning would at least have been plausible; yet in modern times it would have been quoted by Sir Frederick Thesiger as indicative only of the cunning of confirmed insanity, and *malgrè* the prophetic limit, a jury would have found him incapable of managing his own affairs, though the Creator had restored his kingdom as well as his understanding."—p. 168.

DRAFT BILL.

"TO PRODUCE UNIFORMITY OF MEDICAL EDUCATION AND QUALIFICATION, AND FOR THE REGISTRATION OF THOSE LICENSED TO PRACTISE IN MEDICINE."

PREAMBLE.—Whereas it is for the good of all Her Majesty's subjects that the knowledge of physic and surgery should be promoted, and that means should be afforded whereby those who have been examined and found skilful by competent authority may be known from ignorant and unskilful pretenders to the same knowledge: And, whereas the laws now in force concerning the profession of physic and surgery require to be amended: Be it enacted, by the Queen's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by authority of the same:

1. *Repeal of Statutes.*—[3 Hen. 8, c. 11.]—That an Act passed in the third year of the reign of King Henry

the Eighth, intituled, "An Act for the appointing Physicians and Surgeons;" and also another Act passed in the fifth year of the same reign, intituled "An Act concerning Surgeons to be discharged of Quests and other Things;" and also two Acts passed in the thirty-second year of the same reign, respectively intituled, "For Physicians and their Privilege," and "For Barbers and Surgeons;" and also another Act passed in the Session of Parliament holden in the thirty-third and thirty-fourth years of the same reign, intituled, "A Bill that Persons, being no common Surgeons, may minister Medicines, notwithstanding the Statute; and another Act passed in the first year of the reign of Queen Mary, intituled, "An Act touching the Corporation of Physicians in London;" and also an Act passed in the Session of Parliament holden in the sixth and seventh years of the reign of King William the Third, intituled "An Act for exempting Apothecaries from serving the offices of Constable, Scavenger, and other Parish and Ward Offices, and from serving on Juries;" and so much of every other Act as continues the last recited Act; and also an Act passed in the tenth year of the reign of King George the First, intituled, "An Act for the better viewing, searching, and examining of all Drugs, Medicines, Waters, Oils, Compositions, used or to be used for Medicines, in all places where the same shall be exposed of Sale, or kept for that purpose, within the City of London or Suburbs thereof, or within seven miles circuit of the said City" and so much of another Act passed in the eighteenth year of the reign of King George the Second, intituled, "An Act for making the Surgeons of London and the Barbers of London two separate and distinct Corporations," as does not relate to the separation of the said corporations, or to the master, governors, and commonality of the mystery of barbers of London; and also so much of an Act passed in the fifty-fifth year of the reign of King George the Third, intituled, "An Act for better regulating the Practice of Apothecaries throughout England and Wales," as relates to the examination of apothecaries, or to the qualifications of persons intended to be examined or to qualify themselves under that Act to practice as an apothecary, or to the fees to be paid by apothecaries for the certificate of the Court of Examiners, or to the penalties for practising as an apothecary without having obtained such certificate; and also so much of an Act passed in the sixth year of the reign of King George the Fourth as enacts, that all members and licentiates of the Royal College of Physicians in

London actually practising; all surgeons being members of the Royal Colleges of Surgeons in London, Edinburgh, or Dublin, and actually practising; all apothecaries certified by the Court of Examiners of the Apothecaries' Company, and actually practising, shall be freed and exempt from being returned, and from serving upon any juries or inquests whatsoever, and shall not be inserted in the lists to be prepared by virtue of that Act; and also so much of any Act or Charter granted before the passing of this Act as prohibits any person from practising physic or surgery in any place without such license as is mentioned in such Act or Charter respectively, or as imposes any restrictions on the practice of physic or surgery other than is contained in this Act, shall be repealed and annulled.

II. *Interpretation Clause.*—[To be inserted when the Bill is completed.]

III. *Appointment of the Medical Council for England.*—That a Council shall be established, which shall be styled—"The Medical Council for England;" and that the Regius Professor of Medicine in the University of Oxford, the Regius Professor of Physic in the University of Cambridge, such one person as shall be from time to time designated by the Senate of the University of London, the President of the Royal College of Physicians of England, and the President of the Royal College of Surgeons of England, shall be members of the said Council in right of their several offices and appointments; and that the other members of the said Council shall be five Physicians, to be chosen by the Royal College of Physicians of England, five Surgeons, to be chosen by the Royal College of Surgeons of England, and six medical practitioners, to be appointed by one of Her Majesty's principal Secretaries of State; each of the said appointments to be made within one month after the passing of this Act; and the powers and duties vested in the said Council by this Act, may be exercised and executed by any six members thereof.

IV. *Tenure of Office by Members chosen by the Colleges.*—That every member of the said Council appointed by the said College of Physicians, the said College of Surgeons, and the said Secretary of State shall be entitled to be a member of the said Council for three years, and shall then go out of office, but may forthwith be rechosen; and that upon every vacancy among the members of the said Council, appointed by the said College of Physicians, the said College of Surgeons, and the said Secretary of State, and their successors, the said College of Physicians, or the said College of Surgeons, or the said Secretary of State, as the case may be, shall appoint another person to supply such vacancy.

V. *Appointment of the Medical Council for Scotland.*—[To be inserted hereafter.]

VI. *Tenure of Office by Members of the Medical Council of Scotland.*—[To be inserted hereafter.]

VII. *Appointment of the Medical Council for Ireland.*—[To be inserted hereafter.]

VIII. *Tenure of Office by Members of the Medical Council for Ireland.*—[To be inserted hereafter.]

IX. *Expenses of the Members to be paid.*—That there shall be paid to the members of the said several Councils, such reasonable expenses incurred by the said members in performance of their duties under this Act, not exceeding three guineas for each attendance, as shall from time to time be allowed by the said several Councils.

X. *Each of the said Councils to Elect a President and Vice-President.*—That the said Councils shall, as soon as may be after they shall have been appointed as hereinbefore provided, meet at the following places: that is to say, the Council for England at the building of the Royal College of Physicians in London, the Council for Scotland at the building of the Royal College of Physicians at Edinburgh, and the Council for Ireland at the building of the King's and Queen's College of Physicians in Ireland, and shall each of them elect one of their members to be their president, and another of their members to be their vice-president; and in all cases every question brought before any of the said Councils, shall be decided by a majority of votes, (the president, or, in his absence, the vice-president, having a vote,) and in the event of an equality of votes, the president, or, in his absence, the vice-president, shall have an additional or casting vote.

XI. *Each of the Councils to appoint an Examining Board.*—That each of the said Medical Councils shall, within three months after their first meeting, appoint such fit and proper persons, not being members of the said Councils, as the said Councils may severally choose to form an Examining Board for the purpose of carrying into effect the provisions of this Act; and every member of such Examining Board shall be paid such yearly salary as the Council by whom he shall have been appointed shall think fit, and shall hold office for such period as the said Council shall determine.

XII. *Provisions as to the appointment of a Treasurer, Registrar, and Secretary, and of Clerks and Servants, and for the making of a Seal by each of the said Councils.*—That each of the said Councils shall, within a month after their first meeting, appoint a fit and proper person to be their treasurer, and also another fit and proper person to be their registrar and secretary; and there shall be paid to each of such treasurers and registrars such yearly salary as the Council by whom he shall be appointed shall think fit; and each of the said treasurers and registrars shall be removable at the pleasure of the Council by whom he shall have been appointed; and each of the said Councils shall also, from time to time, appoint such clerks and servants as they may deem necessary for the purposes of this Act; and every person so appointed shall be removable at the pleasure of the Council by whom he shall have been appointed, and shall be paid such salary as the Council by whom he shall have been appointed shall think fit; and each of the said Councils shall cause to be made a seal for their use in the execution of this Act, and shall cause to be sealed or stamped therewith all licences

granted or issued by them in pursuance of this Act, and all such licences and other documents purporting to be sealed or stamped with any such seal shall be received as *prima facie* evidence in all courts and places whatsoever.

XIII. *As to Registration of Medical Practitioners in practice before the passing of this Act.*—That the registrar of each of the said Councils shall, within thirty days after his appointment, and shall from time to time, till the first day of February, one thousand eight hundred and fifty three, proceed to register, in books to be kept for that purpose, on payment of a fee of five shillings, the name and place of abode, together with a description of the testimonials of every physician, surgeon, and apothecary who shall apply to be registered, and who, prior to the first day of November, one thousand eight hundred and fifty-two, shall have taken a degree in medicine in any English, Irish, or Scotch University, or who shall state his place of abode and apply to be registered, and shall produce his diploma, certificate, or licence, or shall produce a duly attested certificate, or such other proof as shall be satisfactory to the said registrars, of his having obtained a diploma, certificate, or licence to practise as a physician, surgeon, or apothecary, dated prior to the said first day of November, one thousand eight hundred and fifty-two, and granted by any English, Irish, or Scotch College or Hall, or any Corporation, sole or aggregate, in England Ireland, or Scotland, legally entitled to grant the same at the time of the passing of this Act, and also to every person who shall apply for the same, and who was actually practising medicine in England and Wales prior to the first day of August, one thousand eight hundred and fifteen, and who shall sign a declaration according to the form in Schedule A, to this Act annexed, and also to every surgeon and assistant-surgeon of the Army and Navy who shall apply for the same, and whose warrant of appointment bears date prior to the said first day of August, one thousand eight hundred and fifteen, and to every person who shall have been registered as aforesaid, the said registrars shall give a certificate according to the form in schedule C, to this Act annexed, and which certificate shall be in force till the first day of February, one thousand eight hundred and fifty-three, and no longer.

XIV. *Every Person not Registered as aforesaid to present himself before the Council of his country for Examination. Licences to be granted to those duly qualified on payment of a Fee of £ .*—That each of the said Councils shall meet at least once in every three months, for the dispatch of business; and every person not being registered under the provisions of the next preceding section of this Act, who intends to practise medicine after the first day of February, one thousand eight hundred and fifty-three, shall present himself before the Medical Council for the country in which he intends to practise; and if such Council shall consider the person so presenting himself to be properly qualified as hereinafter is mentioned, they shall direct their registrar to grant to such person a licence according to the form in schedule B, to this Act annexed, on payment of a

fee of ———; and every person to whom such licence shall have been granted as aforesaid, shall be entitled to assume the name and title of a Licentiate in Medicine.

XV. *Candidates for Licences to produce Testimonials to the Medical Council.*—That every person who may present himself before any of the said Medical Councils for the purpose of obtaining a licence to practise medicine, shall produce proofs to the said Council that he has attained the age of twenty-one years, and shall also produce such testimonials as shall be satisfactory to the said Council, that he has applied himself to the study of medical and surgical science during a period of four years, and that during the aforesaid period he has passed at least three years in some University or Medical School approved of by the said Council; and that he has attended such courses of dissection, such clinical and other lectures, and such hospital practice, and has passed such several examinations before the Examining Board appointed by the said Council, as the said Council shall from time to time appoint.

XVI. *Triennial Medical Congress to be held.*—That once in every three years each of the said Medical Councils shall depute three of their members to form a Medical Congress, for the purpose of fixing an uniform curriculum of study, in accordance with the next preceding section of this Act, to be gone through by all candidates for licences to be granted by the said Councils respectively; and such Medical Congress shall meet in London at such place and time as the Medical Council for England shall determine; the first Medical Congress to be held as soon as may be after the election of the said several Medical Councils.

XVII. *As to Registration of Medical Practitioners who shall not have been Registered under the Thirteenth Section of this Act.*—That the Registrar of each of the said Councils shall, on and after the first day of November, one thousand eight hundred and fifty-two, proceed to register, in books to be kept for that purpose, and without any payment whatever, the name and place of abode, together with a description of the testimonials of every physician and surgeon who shall apply to be registered, and who shall produce the diploma or licence of the Royal College of Physicians, or the Royal College of Surgeons, of the country in which he applies to be registered, together with the licence of the Medical Council for the same country; and to every person who shall have been registered as aforesaid the said registrars shall give a certificate, according to the form in schedule C, to this Act annexed, and which certificate shall be in force until the first day of February then next ensuing, and no longer.

XVIII. *Registrars to Issue Annual Certificates to Registered Practitioners, on payment of a fee of —s.*—That the Registrars of each of the said Councils shall from time to time issue a certificate, according to the form in schedule C, to this act annexed, to every person who shall be registered as aforesaid, and who shall apply for such certificate; and the said registrars shall issue such certificates for the countries only for which they shall be severally appointed to act; and every person shall, upon his application for such certificate,

pay to the registrar a fee of ———; and such certificate shall bear date on the first day of February then next ensuing, and shall continue in force during one year, and no longer.

XIX. *All Monies received by the Registrars to be applied for the purposes of the Act.*—That all monies received by the registrars of the said several Councils shall be paid over to the Treasurers of the said several Councils, and shall be applied to defray the expenses of carrying this Act into execution, in such manner as the said Council shall direct; provided always that one half of the monies received on account of the certificates hereinbefore mentioned shall be applied to the formation of a Medical Provident Fund for England, Scotland, and Ireland respectively, under the direction of the said several Councils; and every person who shall have been registered under this Act, and shall have obtained a certificate during ten years, or, in case of his death, his widow or children, shall be entitled to claim relief from the Council of that part of the United Kingdom in which he shall have been registered, out of the monies of their Medical Provident Fund.

XX. *Application of Surplus Income.*—That if, after paying the expenses of carrying this Act into execution, any surplus income, other than the monies hereinbefore directed to be applied to the formation of a Medical Provident Fund, shall remain in the hands of the Treasurer of any of the said Medical Councils, such surplus shall be applied for the founding or establishing of medical scholarships or prizes, or in promoting the advance of medical science and literature, in such manner as such Medical Council shall determine.

XXI. *Each Registrar to keep a Record of Certificates.*—That the registrar of each of the said Councils shall duly record an account of every certificate which he shall issue as aforesaid; and in the month of February in every year shall cause to be printed a correct register, in two lists, according to the form in schedule D, to this Act annexed, of the names and places of residence, arranged alphabetically, in each list, of all persons to whom he shall have so issued certificates during the year then last past, according to the provisions of this Act, together with a description of the legal qualification or qualifications, with the date or dates thereof, of all persons registered under the thirteenth section of this Act, and specifying the date of the licence granted by the Council, and the degrees and diplomas with the date or dates thereof, possessed by all persons registered under the seventeenth section of this act; and such registers shall be respectively called, “The Medical Register for England,” “The Medical Register for Scotland,” and the Medical Register for Ireland;” and a printed copy of the Register for the time being, so published as aforesaid, shall be evidence in all courts, and before all Justices of the Peace and others, that the persons therein specified have obtained certificates according to the provisions of this Act; and the absence of the name of any person from such printed copy shall be evidence, until the contrary be made to appear, that such person has not obtained a certificate according to this Act.

XXII. *Registered Persons Entitled to practise where Certificates are Issued; and to Transfer their Names to the Register of other parts of the United Kingdom.*—That every person who shall be registered, and shall possess a certificate in force, according to the provisions of this Act, shall be entitled to practise medicine throughout that part of the United Kingdom for which his certificate was issued; and every person who shall be registered in one part of the United Kingdom may transfer his name to the register of any other part of the United Kingdom in which he may be about to practise, on production to the register of the last-named part of the United Kingdom of his licence and certificate for the current year; and the registrar shall thereupon grant to such person transferring his name a certificate, which shall remain in force till the first day of February then next ensuing.

XXIII. *Registered Persons entitled to Charge for Advice and Visits.*—That all persons, not being physicians, who shall be registered and possess certificates according to the provisions of this Act, shall be entitled to demand and recover in any Court of Law, with full costs of suit, reasonable charges for medical or surgical advice, visits, and medicine, rendered or supplied by them to their patients, without any other licence than such registry and certificates.

XXIV. *None but Registered Persons to Recover Charges.*—That, after the first day of February, one thousand eight hundred and fifty-three, no person shall be entitled to recover any charge in any Court of Law for any medical or surgical advice, attendance, or for the performance of any operation, or for any medicine prescribed, administered, or supplied by him, unless he shall prove upon the trial either that he is in possession of a certificate in force, according to the provisions of this Act, or that he was legally practising in the capacity in which he claims such charge at the time when the debt was incurred.

XXV. *Persons not Possessing Certificates Incapable of Acting as Medical Officers in Public and Other Situations.*—That, after the first day of February, one thousand eight hundred and fifty-three, no person who does not possess a certificate in force, according to the provisions of this Act, shall be capable of holding any appointment in any part of the United Kingdom, in the capacity of a physician, surgeon, apothecary, or other medical officer, in any hospital, infirmary, dispensary, lunatic or other asylum, lying-in hospital, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse, or poorhouse, parish, union, or other public establishment, body or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age.

XXVI. *Summary Penalty against Unregistered Practitioners.*—That, if any person shall, after the first day of February one thousand eight hundred and fifty-three, act or practise as a physician, surgeon, apothecary, or licentiate in medicine, in any part of the United Kingdom, without being duly registered according to the provisions of this Act, and without having a certificate as aforesaid in force at the time of his so

practising or acting as a physician, surgeon, apothecary, or licentiate in medicine, he shall, on conviction before any magistrate having jurisdiction in the county, city, or place where the offence was committed, forfeit and pay a sum not exceeding five pounds, nor less than forty shillings, for every such offence, to be recoverable within three months next after the commission of the said offence.

XXVII. *Expulsion of Registered Practitioners for Disgraceful Conduct, or Irregular Practice.*—That, if three registered practitioners shall at any time complain to the Council of any College or other governing body, that a person who had obtained his licence, diploma, or qualification from such College, or body, had been conducting himself in a manner calculated to bring scandal and odium on the profession, by publishing indecent advertisements or pamphlets, or immoral or obscene prints or books, or had been guilty of any other disgraceful and unprofessional behaviour, or of any irregular practice, the said Council, or other governing body aforesaid, are hereby empowered to cite the person accused before them, first giving him due notice, and a full statement of the charges against him; whereupon the said Council, or other body, having heard the defendant, and on being satisfied that the charges have been proved, or in default of his appearance, having decided that the charges have been proved, they are hereby required to erase the name of such person from the books or rolls of the said College, or other institution as the case may be, and shall transmit forthwith to the registrar of that part of the kingdom to which such College, or other institution belongs, an official report of their decision, authenticated by the seal of such College; and the said registrar shall thereupon strike out the name of the offending party from the register in his custody, and it shall ever afterwards be excluded from every register to be kept under the provisions of this Act, unless the Council, or other governing body by whom the name was first erased shall readmit it into the books or rolls of such College, or other institution. Provided always that the name of no person who may be possessed of a licence granted by a Medical Council according to the provisions of this Act, shall be erased from the register, unless the registrar receive from such Medical Council an official decision to that effect, authenticated by their seal.

XXVIII. *Penalty for the Wilful Falsification of the Record of Certificates by any Registrar.*—That if any registrar under this Act shall wilfully make or cause to be made any falsification in any matters relating to any register, certificate, or record aforesaid, every such offender shall be deemed guilty of a misdemeanor in England and Ireland, and in Scotland of a crime and offence; and shall, on conviction thereof, be sentenced to be imprisoned for any term not exceeding six months.

XXIX. *Penalty for Obtaining Certificate by False Representations.*—That if any person shall wilfully procure or attempt to procure a certificate from any Registrar, by making or producing, or causing to be made or produced, any false or fraudulent representa-

tion or declaration, either verbally or in writing, or shall, by any false or fraudulent means whatsoever, possess, obtain, use, or attempt to possess, obtain, or use, any certificate as aforesaid, every such person so offending, and every person aiding and assisting him therein, shall, upon being convicted thereof, be adjudged guilty of a misdemeanor in England and Ireland, and in Scotland of a crime and offence; and thereupon it shall be lawful for the Court before whom such offender shall be tried and convicted to sentence such offender to be imprisoned, with or without hard labour, for any period of time not exceeding six calendar months.

XXX. Penalty for Falsely Pretending to be a Medical Practitioner.—That every unregistered person who shall wilfully and falsely pretend to be, or take or use the name or title of a physician, doctor, bachelor of medicine, surgeon, or apothecary, or any name, title, addition, or description, implying that he is registered under this Act, or that he is recognised by law as a physician, or surgeon, or apothecary, or a practitioner in medicine, shall, on being convicted of every such offence, before any Magistrate having jurisdiction therein, pay a sum not exceeding ten pounds, nor less than forty shillings, to be recoverable as hereinafter described.

XXXI. How Penalties are to be recovered; if not paid, the Offender may be Committed.—That any Justice of the Peace acting in and for the county, city, or place in which the offence has been committed, or any Magistrate appointed by virtue of an Act passed in the second and third years of the reign of Her Majesty Queen Victoria, intituled “An Act for Regulating the Police Courts of the Metropolis,” or one of the Justices of Peace Courts in Scotland, may hear and determine any complaint charging any person with practising medicine, without a certificate, as aforesaid, on the oath of one or more witnesses, or by the confession of the accused party, and shall award the penalty or punishment herein provided for such offence; and in every case of the adjudication of a pecuniary penalty under this Act, and of non-payment thereof, it shall be lawful for the said Justice or Magistrate to commit the offender to any gaol or house of correction within his jurisdiction, for a term not exceeding one calendar month, when the sum does not exceed forty shillings, and for a term not exceeding three calendar months when the sum does not exceed ten pounds, the imprisonment to cease on payment of the sum due.

XXXII. Application of Penalties.—That any sum or sums of money arising from conviction and recovery of penalties for offences committed against the authority and provisions of this Act, shall be paid to the Medical Council for that part of the United Kingdom in which such conviction shall take place.

XXXIII. Examiners may take Candidates to Hospitals, &c.—That each of the said Examining Boards, or any members or member thereof, shall be empowered to attend with the candidates for licences in the public hospitals, or other public institutions containing sick and diseased persons, and also in any workhouse, with the view of ascertaining the practical knowledge of such candidate in the science of medicine.

XXXIV. Provision for existing Students.—That it shall be lawful for the said several Medical Councils to make regulations for dispensing with such provisions of this Act as to them shall seem fit, in favour of Medical Students who shall have commenced their professional studies before the passing of this Act.

XXXV. Act not to affect the Trade or Business of Chemists and Druggists.—That not anything in this Act contained shall extend, or be construed to extend, to prejudice or in any way affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing and vending, drugs, medicines, and medicinable compounds, wholesale or retail, without the giving of medical or surgical advice.

XXXVI. Registered Medical Practitioners exempted from serving on Juries, Inquests, &c.—That every person who shall be registered and possess a certificate in force, under the provisions of this Act, shall be exempt, if he shall so desire, from serving on all juries and inquests whatsoever, and from serving all corporate, parochial, ward, hundred, and township offices, and in the Militia, and that the name of such person shall not be returned in any list of persons liable to serve in the Militia, or in any such office as aforesaid; and no person shall be entitled to such exemption as aforesaid, on the ground of being a physician, surgeon, or apothecary, who does not possess such certificate then in force, as aforesaid.

XXXVII. For certain Offences, names of Medical Practitioners to be erased from the Register.—That if any registered medical practitioner shall be convicted in England or Ireland of any felony, or in Scotland of any crime or offence inferring infamy, or the punishment of death or transportation, or if it shall be found, by the judgment of any competent Court, that any such medical practitioner shall have procured a certificate under this Act by any fraud or false pretence, or that any such medical practitioner has wilfully and knowingly given any false statement, evidence or certificate, in any case in which by law the evidence or certificate of a physician, surgeon, or apothecary is required, the registrar of each of the Medical Councils, on the production before him of an office copy or extract of the conviction or judgment of the Court, duly certified under the hand of the proper officer of the Court, or other proof thereof, shall cause the name of such medical practitioner to be erased from the register; and every person whose name shall have been so erased after such conviction or judgment as aforesaid, shall thereby forfeit and lose all the privileges of a registered medical practitioner provided by this Act.

SCHEDULE A.

Declaration required of a person who claims to be registered as a medical practitioner upon the ground that he was in practice as a medical practitioner before the first day of August, 1815:—

To the Registrar of the Medical Council for England.

I, [Samuel Baker,] residing at [6, Duke Street, Exeter,] in the county of [Devon,] hereby declare that I was practising as a medical practitioner, at [16,

George Street, Hastings,] in the county of [Sussex,]
before the 1st day of August, 1815.

(Signed) [SAMUEL BAKER.]

Dated this [6th] day of [November,] 1852.

SCHEDULE B.

Licence to Practise Medicine.

This is to certify that [Herbert Jones] has been carefully and deliberately examined as to his skill and abilities in the science and practice of medicine, and as to his fitness and qualification to practise the same, by the Examining Board appointed in pursuance of an Act of Parliament passed in the [] year of the reign of Her Majesty Queen Victoria, intituled "An Act to produce Uniformity of Medical Education and Qualification, and for the Registration of those Licenced to Practise in Medicine;" and the Medical Council for [England] have, by virtue of the powers vested in them by the said Act, directed this Licence to be granted to the said [Herbert Jones,] certifying that he is duly qualified to practise medicine.

(Signed) [JOHN FAIRBROTHER,]
President of the Medical Council for [England.]

(Signed) [HENRY BROWN,]
Registrar of the Medical Council for [England.]

Dated this [3rd] day of [March,] 185 .

SCHEDULE C.

The Medical Register for [England].—Medical Registration Certificate for 185 .

In accordance with the provisions of an Act of Parliament, passed in the [] year of the reign of Her Majesty Queen Victoria, intituled, "An Act to produce Uniformity of Medical Education and Qualification, and for the Registration of those Licenced to Practise in Medicine," I hereby certify that [James Howard], residing at [No. 15, Ormond Street, Manchester,] in the county of [Lancaster,] having been in practice prior to November, 1852, and having produced before us some one of the Diplomas or Licences specified in Clause 13th of the said Act, or having signed before me a Declaration according to the form in Schedule A to the said Act annexed;—or not being in practice prior to November 1852; having produced before me the Diploma of [the Royal College of Physicians of England] granted to him [April 18th, 185], as a Fellow of that College, or the Diploma of the Royal College of Surgeons of England, granted to him [March 6th, 185], as a Member of that College, together with the Licence of the Medical Council for [England,] granted to him the [4th] day of [February,] 185 ,) he has been duly registered, according to the provisions of the said Act, as a person who is qualified to practise Medicine in any part of [England and Wales,] and that he is entitled to exercise all the powers and privileges conferred by the said Act.

This Certificate to remain in force until the 1st day of February, 185 , and no longer.

(Signed) [HENRY BROWN,]
Registrar of the Medical Council for [England.]

Dated this [1st] day of [February,] 185 .

SCHEDULE D.

The Medical Register for [England], consisting of the names and places of residence with a description of the qualifications and the dates thereof, of all persons legally qualified to practise medicine in [England,] in the year 185 .

The Names of Registered Medical Practitioners, arranged in two lists as Physicians and Surgeons.

PHYSICIANS.

(Arranged Alphabetically.)

NAMES.	Qualifications and their Dates.	Places of Residence.
ADDISON, JAMES	Diploma as a Fellow of the Royal College of Physicians of England, dated 9th August, 1836	No. 16, Tudor Street, Manchester.
ADLARD, HUGH	Diploma as a Graduate of the University of Edinburgh, dated 3rd April, 1843	No. 7, Milton Street, London.
ADNEY, RALPH	Diploma as a Member of the Royal College of Physicians of England, dated 2nd of May, 1854; Licence from the Medical Council for England, dated 5th July, 1853	The Grove, Camberwell.

SURGEONS.

(Arranged Alphabetically.)

NAMES.	Qualifications and their Dates.	Places of Residence.
ADPART, EDMD.	Diploma as a Fellow of the Royal College of Surgeons of England, dated 4th September, 1838	No. 40, Tolville Street, Leeds.
ADWIN, GILBERT	Declaration as required by Law, of having practised as a Medical Practitioner before the 1st day of August, 1815	No. 19, Milsom Street, Manchester.
ANDREWS, JOHN	Licence of the Society of Apothecaries, London, dated 11th June, 1834	No. 8, Hilton Street, Liverpool.
APPLETON, WM.	Diploma as a Member of the Royal College of Surgeons of England, dated 2nd July, 1814; Licence from the Medical Council for England, dated 5th May, 1853.	No. 90, George Street, Exeter.

Proceedings of Societies.

CREWKERNE AND YEOVIL MEDICAL ASSOCIATION.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I enclose the report of the proceedings of the Crewkerne and Yeovil District Medical Association, at the third general meeting of the members, held at South Petherton, April 8th, 1852, and shall feel obliged if you will give insertion to that part of it which is likely to be of more than local interest.

Your obedient servant,
G. F. WILLS, Hon. Sec.

After the general business of the Association had been transacted, the Draught of the new Medical Bill was read, and much discussion took place respecting its principles and the various clauses. It was agreed, therefore, to discuss each clause separately, and accord-

ingly special consideration was given to every point of the measure, which in general was approved of.

Clause 14.—The meeting considered that the fee for examination and licence to practise should not be less than £25, instead of £10, as proposed; as it is advisable not to lessen the general expenses of a professional education.

Clause 17 was unanimously disapproved of. It was considered that the medical profession was already suffering under too many burdens in the shape of taxes on their industry; and that the payment of twenty shillings annually was unnecessary and unjust. It was thought that five shillings was a sufficient annual registration fee, but that for the first year the amount may be higher. The members consider that, although the proposed provident fund may be useful, it should not be compulsory for medical men to subscribe to it, and therefore that the reason given by the Editor of the *Provincial Journal* (page 74) for the annual fee of 20s., is not satisfactory.

Clause 26.—The members, cordially approving a clause which shall afford an easy method of recovering a "summary penalty against unregistered practitioners," consider the above clause inefficacious in preventing the evils arising from the administration of medicine by ignorant unlicensed persons, who take upon themselves to prescribe and give medicines for any and every complaint, thereby frequently aggravating disease, and not seldom causing illness, mild and tractable at first, to run an unchecked course and terminate fatally, or even directly producing death by maltreatment. The meeting considers that a fuller interpretation as to what constitutes the practice of a "physician, surgeon, apothecary, or licentiate in medicine, surgery, or midwifery," should be given.

Clause 36.—Was considered insufficiently stringent, as it does not prohibit a druggist from preparing and dispensing drugs ordered by himself and administered to a person labouring under sickness.

The meeting consider that there should be a clause introduced requiring the governing body to prosecute unregistered practitioners in certain cases, or they fear lest the example set by the Apothecaries' Company, of not maintaining the rights and privileges of their members, may be followed. The members also believe that it is desirable to make medical education as complete as possible, and the majority are of opinion that the system of pupilage is good, although they would prefer the term of three or four years to five years. It was also suggested that it would be advisable for medical students to pass a session at a recognised hospital at an early period of their pupilage, and not allow the three years attendance at a hospital to remain until the end of their term, as more can be learnt from attending private practice, after a time passed in learning the theory of medicine and surgery at a large hospital where lectures are delivered.

Considerable discussion took place on the subject of friendly societies, and the loss caused by some of them to medical men. It was stated that at Crewkerne the medical gentlemen had unanimously resolved to discon-

tinue contract attendance on tontine and tradesmen's clubs.

The answers received from the Colleges of Physicians and Surgeons, and from the Apothecaries Company, in reply to the communications addressed to them by a committee appointed to request them to take measures against illegal and empirical practitioners, were read and considered to be most unsatisfactory.

Foreign Department.

GERMANY.

The following extracts are taken from the *Verhandlungen der Physikalisch-Medicinischen Gesellschaft in Würzburg*:—

On the Nerves of Bone.—M. Koelliker states that in the human subject the nerves accompany the blood-vessels not only in the medulla of the long bones, but also in the spongy tissue of the epiphyses. The short bones, such as the vertebrae are richly supplied with nervous filaments, as are also the blade-bones and ilia. They are also readily demonstrated in the bones of the cranium. The function of these nerves he considers to be chiefly that of nutrition; but that they contain sensitive fibres is plainly shown by the pain which attends disease of osseous structure.

Vibratile Cells in the Bronchial Membrane of Man.—One of the most curious revelations of the microscope is the existence of epithelial cells, the free surface of which is covered by extremely fine ciliae, presenting, during life and immediately after death, a vibratile motion. M. Biermer has seen this curious phenomenon in the bronchial membrane of a man dead of phthisis; and by sprinkling the surface with charcoal, was enabled to see that the molecules were uniformly moved from below upwards, proving that the epithelial ciliae moved in that direction.

Histological Elements of False Membranes.—M. Virchow enumerates these as follows:—1. *Connecting tissue.* This is formed out of an amorphous fibrinous coagulum, which is susceptible of various forms, but chiefly affecting that of fibre. After a certain period this fibrinous coagulum is found to be entirely converted into connecting tissue, composed of slender corpuscles, which are easily resolved into minute fibrils, containing an elongated nucleus, with distinct nucleoli. In many portions of false membrane the structure remains entirely amorphous.—2. *Elastic fibres* are found in some membranes, but not in all. The author has generally seen them in those of the pleura, and seldom in those of the uterus. In old adhesions these fibres are toothed, and in some cases are so numerous as to be visible to the naked eye, as white lines.—3. *Vessels.* The author has repeatedly injected false membranes, both from arteries and veins. The degree of vascularity depends very much on the nature of the organ to which the false membranes are attached, as does also the preponderance of arterial or

venous capillaries. Thus the adhesions between the liver and diaphragm are more freely injected from the vena porta than from the hepatic artery. The author remarks upon this fact as of importance in reference to the circulation, inasmuch as a certain quantity of blood may thus reach the heart, without having undergone depuration by the liver.—4. *Nerves*. The author has only succeeded in tracing nervous filaments into false membranes in a very few instances.

Ununited Fracture.—Professor Blasius treats ununited fracture by the local application of iodine. He has recently detailed two successful cases, one of a soldier, in whom the ends of the fractured tibia and fibula had remained moveable for six months; the other a case of fractured femur. He pencilled the locality of the fracture with the following solution:—Jodini, scr. j.; Potassii Iodidi, dr. ss.; Sp. Rect., oz. j. Consolidation took place in three weeks in the first case, and in thirteen weeks in the second.

Absence of the Fœtus in early Abortion.—Dr. Meyer (*Henle's Zeitschrift*) mentions the frequent occurrence of discharged ova in which no fœtus can be found. In external appearance the mass resembles a coagulum of blood, which, when cut into, contains a cavity lined by a smooth membrane, which is evidently the amnion. A funis is also found, with a free extremity, which looks as if it had been torn across. No fœtus, however, is to be discovered. Dr. Meyer, not satisfied as may be imagined, with the surmise that the fœtus was never present, has searched in these instances, and always found a rent on one or other aspect of the ovum, generally directly opposite the insertion of the funis. It is clear, therefore, that the fœtus has escaped through this orifice, and, being small, easily escaped observation.

[A specimen of this kind was recently exhibited at the Norwich Pathological Society, by Mr. Eade, of Blofield, exactly corresponding with the description above given. In this case, though the fœtus could not be found, there were symptoms which pointed out that something had been expelled some days prior to the abortion of the remainder of the ovum.]

General Retrospect.

PRACTICAL MEDICINE.

Treatment of Paraplegia by Ergot of Rye.—By Mr. WHITE.

Mr. White speaks of a case of paraplegia occurring in a farmer, who had lost the use of his lower extremities, in consequence of exposure to cold and damp. The paralysis commenced, as it frequently does, by pricking pains in the legs. The treatment was commenced by blisters to the spine, and mercury to salivation, under which a certain amount of amendment took place, but he was still unable to walk, though he could stand. Here the improvement ceased, and the author then gave him strychnine, with still further benefit; but this time the improvement was not maintained, he lost strength, the bowels became obstinately costive, and he

lapsed into a condition apparently hopeless. At this juncture the author was induced to give him ergot of rye, having seen its powers in paralysis highly eulogised by M. Gerard. The dose was half a drachm three times a day in an electuary. When an ounce had been taken it was observed that the bowels had begun to act spontaneously, then he commenced to have increased power over his paralyzed limbs, and in one month from the commencement of the medicine he was able to walk a mile without assistance.—*Dublin Medical Press*, April 14, 1852.

On the Mode of Distinguishing between Calculi of Uric Acid and Urate of Ammonia.—By Mr. L. LAWRENCE.

Mr. Lawrence states that he has found, experimentally, that the rules for making the above diagnosis, which are generally laid down in books, are not absolutely sufficient for the purpose. The ordinary tests are—

"1. Urate of ammonia is distinguished from uric acid by evolving ammoniacal fumes in treating the fragment of the calculus with caustic potash." This test, according to Mr. Lawrence, is not often available in determining the character of the necessarily small quantities the analyst of calculi has to deal with; and moreover, uric acid itself, in common with other nitrogenised animal substances, might of itself evolve ammoniacal fumes on being treated with a concentrated solution of potash.

"2. An aqueous solution of uric acid does not give the murexide test; an aqueous solution of urate of ammonia does." This statement, in his opinion, requires qualifying, in so far that, while this is true of cold solutions, it is not true of boiling solutions, which give the test with both the substances under consideration.

"3. A cold aqueous solution of uric acid yields no precipitate on the addition of hydrochloric acid; a similar solution of urate of ammonia does." This he considers perhaps the best of all the tests yet mentioned, though it is omitted in many books.

To these the author adds a test which, long applied as it has been to the recognition of urinary deposits, has not, as far he is aware, been made use of in the analysis of urinary calculi. "A small fragment of the calculus is reduced to a fine powder and boiled for a minute or so in distilled water, and a single drop of the solution, placed on a plate of glass, examined microscopically. If it be uric acid, a multitude of well-defined crystals make their appearance as the drop cools; the various forms of these crystals are well figured in Bowman's 'Medical Chemistry.' Should, on the contrary, the substance be urate of ammonia, no crystals are seen, but those amorphous aggregations of globules, generally of a brownish tint, so familiar to the examiner of urinary sediments, will be perceived. Even the naked eye will readily distinguish the glistening crystalline precipitate of uric acid from the dull amorphous one of urate of ammonia. It is only in solutions of urate of ammonia which have stood for some time that I have been able to detect crystals, which were then of an entirely different character from those of uric acid." In conclusion, the author remarks that while this last test does not yield to any of the others in delicacy and precision, it will solve a problem which

none of the others can do, namely, that of detecting mixtures of the two substances in question.—*Medical Times and Gazette*. March 27.

Tetanus cured by the Inhalation of Chloroform.—By
DR. BANKS.

The patient had received a severe kick in the face, nine days prior to the commencement of the tetanic symptoms (August 9th), he was also exposed to wet and cold. On admission he was in a fully developed tetanic state. The sterno mastoid muscles were rigid and the head drawn back. He had complete opisthotonos and the abdominal muscles were tense and hard. Croton oil was given and a quarter of a grain of belladonna was ordered every two hours. On August 15th the jaws were permanently locked, respiration extremely difficult, and the body bedewed with perspiration. A grain of Indian hemp was given every hour, without any relief, when, on the 16th and 17th it was determined to let him inhale chloroform, which he did to perfect insensibility. On recovering his consciousness, the patient was able to open his mouth to the extent of an inch, and swallowed with ease, and expressed himself much relieved. The inhalation was resumed on the 18th, with still further amelioration, and after a few days longer treatment by the same means, the spasm entirely subsided.—*Dublin Quarterly Journ. of Medical Science*, February, 1852.

SURGERY.

Peculiar Diagnostic Symptom in Rheumatic Ophthalmia.

Mr. Canton mentions a symptom which he has so constantly seen associated with this complaint, that he considers it will materially diminish the difficulty of diagnosis in doubtful cases. The symptom alluded to is a white deposit which collects at the internal canthus of the lids. It is most abundant where the urine contains a copious deposit of lithates. Sometimes he has observed it to be associated with pains in the limbs and larger joints.—*Lancet*, March 27, 1852.

Death from Chloroform.

[Another has been added to the number of cases, which show that this powerful agent is not to be used without the greatest caution, and that there are no certain indications by which the probability of its unsuitableness in a given case can be predicated. Dr. Snow has informed us that the only certain way of obviating similar accidents to the present, is by diluting chloroform with alcohol; and as the effects of the mixture, though not so speedy, are equally certain, it would seem imperative on surgeons not to persevere in the use of the concentrated article. The case is as follows:—]

Thomas Hayward, a rather spare and weakly man, aged 23, was admitted on Thursday, the 29th of January, 1852, under the charge of Mr. Lloyd.

The patient applied to the hospital for an aneurism by anastomosis occupying the whole of the right ear, and also to a considerable extent the soft parts in front and behind that organ. On and behind the ear the vascular growth was elevated so as to form a large

tumour. The integuments of the ear, as well as the diseased mass, were of a deep purple colour. In every part there was strong pulsation, as well as a loud aneurismal murmur; the temperature, however, was much the same as that of the surrounding parts. Projecting from the meatus there was a polypus or large fungus, whence issued a copious purulent discharge, which was often tinged with blood. Pain in the head was complained of, but no unpleasant sensations had been felt in the tumour itself.

The disease had existed since the patient was four years of age. Various remedial means had been employed at different times, but without benefit. The patient had been treated at some of the London hospitals, where setons were introduced into different parts of the tumour, and portions of it enclosed with silver wires, which were now and then twisted so as to tighten them, but these measures were of no avail, and at length the patient was discharged as incurable.

Mr. Lloyd, not deeming the cure hopeless, and having consulted with his colleagues, determined to attempt the obliteration of the tumour—first, by deligation of the principal arterial branches in direct communication with the diseased mass, and afterwards by pressure applied to different parts in succession. With this view, on the 14th of February, 1852, the patient was placed under the influence of chloroform, and with the assistance of Messrs. Wormald and Paget, Mr. Lloyd placed a ligature around the temporal artery, just as it passes over the zygoma; other ligatures were applied in such situations as it was considered would tend most to cut off the supply of blood from the part affected, and pressure afterwards used before and behind the ear. The operation lasted, as was expected, for a long time, and the patient was kept under the influence of chloroform for *half an hour, or more*. From the effect of the anæsthetic agent he recovered quickly, and when visited half an hour afterwards he was found lying comfortably in his bed, and on being asked how he was, he answered, "Very well," and smilingly added, "that he was very thankful the operation had been performed, and hoped it could soon be repeated."

After this everything went on favourably; the tumour became much diminished in size, and the pulsation much lessened, but on further examination a large artery was found, beating very strongly, between the mastoid process and the ramus of the jaw, pressure on which part completely arrested the pulsation throughout the diseased growth. On this vessel, therefore, Mr. Lloyd determined to place a ligature, and appointed the 17th of March for the purpose.

The patient was taken into the theatre of the hospital, placed on the operating table, and chloroform administered as on the former occasion. The anæsthetic fluid now used was from the same bottle as had been employed before, and the apparatus was also the same as usual. The chloroform was administered by one of Mr. Lloyd's dressers, who well understood, and had long had experience in its use. A gentleman of great experience, who has been a long time at the hospital, and two years house-surgeon, was watching the patient, and marking the state of the pulse. Other gentlemen were also assisting.

In from five to ten minutes the usual effect was produced, the patient having previously struggled much. The operation was then commenced, but no sooner had Mr. Lloyd cut through the skin than it was stated that the pulse had suddenly stopped.

The chloroform was at once removed, but in a few seconds the patient had ceased to breathe, and no pulsation could be felt in any of the arteries, or at the heart. Artificial respiration, as well as percussion and compression of the different parts of the body, were immediately employed, with energy, and after continuing the means for a short time, the circulation was observed to be returning, and the act of respiration was several times performed; the state of inanition, however, speedily returned, but by the employment of the same means as before, with the use also of galvanism, the circulation and respiration were again restored, but the patient fell quickly into the same state as at first, and was again brought round by the same means. In a few moments the patient relapsed for the third time, when one of Mr. Lloyd's colleagues, coming into the theatre, recommended that the external jugular vein, which on the right side was turgid, should be opened, that tracheotomy should be performed, and the lungs inflated. These means were accordingly had recourse to. The patient was, besides, placed in a warm bath, at the temperature of 104° , artificial respiration being kept up all the time, and friction employed. All, however, was of no avail, and it soon became evident that life was irrecoverably gone.

The resuscitating measures had been continued for more than an hour. Ammonia had been applied to the nostrils, but no attempt was made to introduce any stimuli into the stomach, as Mr. Lloyd feared any liquid placed in the mouth might pass into the larynx, and occasion instant suffocation.—*Lancet*.

Remarks on the Exhibition of Chloroform.—By W. BIRD HEREPATH, M.D.

Alluding to the above melancholy case, Dr. Herapath informs us that he has been particularly free from the accidents which some have experienced in the use of chloroform, and he attributes his immunity to the following precautions:—1st. Never to administer it to any patient with a full stomach. 2ndly. To take particular care that the vapour is diluted with plenty of atmospheric air, invariably employing a cupped sponge, with large holes, applying but a small quantity of the liquid at one time. 3rdly. Never to proceed to stertorous respiration, if it can be avoided. As soon as the patient becomes insensible to sound, or the pupils dilate, to intermit the application of the chloroform, and operate at once, if necessary applying the sponge again and again, for short periods, in order to keep up the anæsthetic effect. It is never necessary, he observes, to make the patient lie like a breathing log, as is known to occur in the practice of other parties. Death from chloroform takes place in consequence of the density of the air mixed with the heavy vapour of the chloroform being nearly equal to or greater than that of the carbonic acid to be expelled from the blood: thus, the density of carbonic acid gas at 60° is one and a half that of atmospheric air; consequently, oxygen and nitrogen endosmose through the membranes of the pulmonary air-cells and capillaries, whilst carbonic acid exosmose

through the same membranes, according to the known laws regulating endosmosis of gases—namely, “in inverse proportions to the square roots of their densities.” Now, increase the density of the inspired air by adding the vapour of chloroform to it, and of course carbonic acid accumulates in the circulating fluids; it does not exosmose through the membranes at the same rate. The nearer the two densities correspond, the less carbonic acid escapes from the blood, and the function of respiration no longer goes on. There is another circumstance worthy of attention. Atmospheric air at 60° saturated with the vapour of chloroform, has a specific gravity of 1.355, and is therefore perfectly respirable; but increase the temperature of the air to 70° , and it will take up a much larger quantity of the vapour, by which means the specific gravity will be increased to 1.533. It is, therefore, necessary to pay attention to this point also, or danger will ensue. This is more especially requisite where inhalers are employed; a good cupped sponge, moistened with cold water, has, in Mr. Herapath's opinion, numerous advantages over every variety of inhaler, the chief being, that the rapid evaporation of the chloroform diminishes the temperature of the air, as it passes through the interstices of the sponge, thus decreasing the specific gravity of the mixed gases for respiration, and consequently adding to the safety of the patient.

There are, he continues, other causes why chloroform impedes and destroys the powers of life. The local anæsthetic effect of the vapour upon the ramusculi of the pneumogastric nerves, distributed on the air-cells, destroys their excitability; they no longer carry that excito-motory power to the medulla oblongata, so necessary to produce the mechanical movements of the respiratory phenomena; consequently the motor nerves no longer stimulate the respiratory muscles to action. Again, the blood, highly charged with chloroform and carbonic acid, and deficient in oxygen, may act centrally on the medulla oblongata, destroying its nervous energy and paralyzing its functions.

In resuscitating from an over-dose of chloroform, Mr. Herapath considers galvanism to be the only chance. His advice is to keep up a current of electricity through the fifth nerve, medulla oblongata, phrenic nerves, and diaphragm, as long as respiratory movements can be produced, and to let the patient have plenty of fresh air or oxygen gas; the case, then, must do well, for the blood will remain fluid for a long time, and circulation will go on as long as respiration continues to be carried on artificially. The blood and the air cells throw off their load, and in proportion as the pneumogastric, medulla oblongata, and motor nerves, slowly resume their functions, so respiration begins to assume a less artificial character; at length the cerebrum aids us, and respiratory movements, both voluntary and involuntary, keep up the functions of life unaided.—*Lancet*, March 27.

M I D W I F E R Y.

Ovarian Dropsy; Partial Removal of the Cyst.—By MR. BROWN.

The occasional recovery, after spontaneous rupture of the ovarian cyst, and extravasation of its contents into the peritoneal cavity, has led Mr. Brown to devise an

operation intended to imitate the results of these accidents, which operation consists in the removal of a portion of the cyst after evacuation of its contents, returning the remainder into the abdomen. The progress of the case is as yet unknown.

The patient is a woman, about 40 years of age, following the occupation of servant, and who has been suffering from ovarian dropsy for several years past. She had spent some time in another hospital, whence she was discharged as incurable, being told that tapping would be of no benefit to her; she, therefore, now objected to this ordinary means of removing the fluid.

Chloroform was administered by Dr. Snow, first with his inhaler, and afterwards with the simple sponge, the insensibility remaining complete all through the operation. The patient's abdomen is very prominent and pendulous, the skin being of a rather dark tinge, and permeated with large veins. Mr. Brown made his incision in the mesial line, commencing a little below the umbilicus, and descending in a straight direction for about four inches. All the layers, down to the peritoneum, were carefully divided, and the latter slit open with the assistance of the director. The cyst, of a light grey colour, now came into view, bulged out by the fluid, and Mr. Brown passed his finger easily between the cyst and parietes of the abdomen. It was now plain that no adhesions existed between these parts, for the whole hand of the operator was easily glided all round the cyst between the latter and the walls of the abdomen. It struck some of the spectators that this great freedom from adhesions might perhaps be favourable to the complete removal of the cyst. Mr. Brown now introduced the trocar and canula in the centre of the exposed portion of the cyst, and evacuated about a gallon of very clear limpid fluid, the cyst being all this while held by an assistant with a vulsellum, so as to prevent its collapse. After the removal of the fluid, Mr. Brown raised, with the vulsellum, a portion of the cyst, about the size of the palm of the hand, and removed it by a horizontal section with the scalpel.

A little fluid which had collected during this process was now allowed to escape, and the cyst pushed back into the abdomen. The margins of the cutaneous section were brought together, and secured by six sutures, a compress applied, and a wide roller placed around the abdomen. Very little blood was lost during the operation, and none at all on the section of the cyst.—*Lancet*, March 13.

TOXICOLOGY.

Case of Poisoning by Atropin.—By Dr. ANDREWS.

The subject of this case was using a solution of atropin for iritis, and by mistake took a mouthful of it instead of a bitter mixture. She immediately became sensible of heat in the throat, and in a few minutes her eyesight began to fail, her voice was too feeble to be heard, and soon after she became unconscious. The nurse immediately gave her large quantities of milk, which induced vomiting. She was seen by the clinical clerk fifteen minutes after taking the poison. The

pupils were widely dilated; face flushed; and the muscles twitched; pulse 130. She was restless, turning constantly in bed, and, except when spoken to, was silent. On attempting to walk she staggered. Vomiting was maintained by sulphate of zinc. In spite of this, drowsiness came on, and, increasing in intensity, she was ordered ammonia, and galvanism was to be resorted to if necessary. Next day she had some shivering, and lapsed into a state closely resembling delirium tremens. Towards evening the violence became so great that restraint was required. She talked incessantly and frequently spit about the bed. The pulse was quick, the eyes bloodshot, and the pupils still dilated. On the following morning she was quieter, but one eyelid was observed to be slightly paralyzed. Her state remained precarious for several days, during which various symptoms affecting vision were complained of. She, however, gradually recovered. It was calculated that she had swallowed about two-thirds of a grain of atropin.—*Edinburgh Monthly Journal*, January, 1852.

Medical Intelligence.

TESTIMONIAL OF RESPECT.

Mr. E. H. Ambler, M.R.C.S. and L.A.C., on leaving his situation, as assistant to Robert Pookes, Esq., of Stalbridge, Dorset, has been presented by the inhabitants with a handsome silver coffee-pot and tea service as a testimonial of esteem for his private character and professional services during a residence of upwards of seven years. The coffee-pot bears the following inscription:—

"To Edward H. Ambler, Esq., M.R.C.S., with a silver tea service. A parting token of esteem for his professional and personal character from Stalbridge and adjacent parishes.—1852."

APPOINTMENTS.

Mr. George Alfred Sheppard has been elected House-Surgeon to the Worcester Infirmary, by a majority of 119 votes. The election took place on Monday, the 3rd instant.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 23rd ultimo:—George Barnard, Bath; Samuel Elwin Brand, Aldersgate Street; Robert Newcombe Day, Chudleigh, Devon; William Henry Dodwell, Hammersmith; Henry James Gane, Bath; Frederick Abner Gange, Dover; Joseph John Hill Gramshaw, Bristol; Robert Hulis, Limehouse; Francis Legerson Hoare, Cahersiveen, Kerry; William Edward Masfen, Stafford; Thomas Hopkins Mercer, Alderley, Gloucestershire; Robert Bryant Pearce, Bath; Nicholas Warburton White, Macroom, county Cork; John Wills, Donhead, St. Andrew, Wilts.

The following gentlemen were admitted members on the 30th ultimo:—Richard Banbury, Launceston, Cornwall; Richard Barnett, Belfast; William Charles Rockett, Walworth; Horatio Costerton, Weymouth, Dorsetshire; Warren Jane, Chepstow, Monmouthshire; Robert Toulmin Leeming, Lancaster; William Webb, Barton-under-Needwood, Staffordshire; Robt. Whitley, Bedford Square.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on the 22nd ultimo :—Edward Burman Adams, Bungay, Suffolk; Henry Baker Armstrong, Brecon, South Wales; George Atfield; Robert Butterfield Cumming; Wm. Duncan, Amble, Northumberland; Benjamin Godfrey, Grosvenor Place, Camberwell; Louis Lawrence Smith; John Hender Tickell.

Gentlemen admitted members on the 29th ultimo :—George Butler, Brighton; John Edward Davies, Stones End, Southwark; Horace E. Johnson, Warwickshire.

NAMES OF GENTLEMEN WHO PASSED THE PRELIMINARY EXAMINATION IN CLASSICS AND MATHEMATICS AT APOTHECARIES' HALL, APRIL 27 AND 28.—George William Fleetwood Bury, Whetstone; Rinso Robert Siccama, London; Richard Unthank Wallace, Hackney; Henry Townsend Whiting, London; R. H. Haynes, London; George J. Wood, London; Theodore Davis, Birmingham; Frederick Lawrance, Twickenham; Edmund Valentine, Somerton; Alfred B. Daffin, London; William Allis Smith, Birmingham; Edward Arthur Page, London; Edward Livesey Dixon, London; Newton Heelas, Woking; Samuel Giles, London; Lewis Horne, London; John Rogers, London; John Moses Bateson, London; William L. Wyman, London; Herbert Barnes, London; Jesse Henry Hall, Louth; Edward Hooper May, Tottenham; Joseph James Muskett, Norfolk; Robert John Sprakeling, Canterbury; Paul Henry Stokoe, Peckham; William R. Hooper, Bath; Montague J. UNIVERSITY OF LONDON.

The following are the names of the candidates who have obtained honours, scholarships, exhibitions, medals, and prizes, in 1851 :—

DOCTOR OF MEDICINE.

R. Growse, Guy's Hospital.—Gold medal for a Commentary on a case in medicine.

BACHELOR OF MEDICINE.

Honours in Physiology and Comparative Anatomy.—J. R. Reynolds, University College, University medical scholar and medalist; D. H. Monckton, King's College, medalist; W. Odling, Guy's Hospital; E. A. H. Head, King's College.

Honours in Surgery.—E. A. H. Head, King's College, University medical scholar and medalist; H. Thompson, University College, medalist; J. R. Reynolds, University College; G. May, King's College; J. S. Stocker, Guy's Hospital.

Honours in Medicine.—J. R. Reynolds, University College, University medical scholar and medalist; H. Thompson, University College, medalist; E. A. H. Head, King's College; J. S. Stocker, Guy's Hospital;

Honours in Midwifery.—H. Thompson, University College.

Honours in Chemistry.—W. Roberts, University College, prizeman; H. S. Lambert, Queen's College, Birmingham.

Honours in Animal Physiology.—W. Roberts, University College, prizeman; G. Buchanan, University College; E. Fry, University College; J. Beddoe, University College; H. C. Oats, University College; J. Rae, University College.

Honours in Vegetable Physiology and Structural Botany.—G. Buchanan, University College, W. Roberts, University College, (Equal).

FIRST EXAMINATION FOR THE DEGREE OF BACHELOR OF MEDICINE.

Honours in Anatomy and Physiology.—T. Hillier, University College, exhibitor and medalist; J. W. de Tunzelman, University College, medalist; W. Roberts, University College; J. Ekin, University College; W. E. Robbs, King's College; J. Ramskill, Guy's Hospital; H. V. Carter, St. George's Hospital; J. N. Winter, Guy's Hospital.

Honours in Chemistry.—W. Roberts, University College, exhibitor and medalist; J. Ramskill, Guy's Hospital, medalist; T. Hillier, University College; J. W. de Tunzelman, University College; H. V. Carter, St. George's Hospital.

Honours in Materia Medica and Pharmaceutical Chemistry.—J. Ramskill, Guy's Hospital, exhibitor and medalist; J. W. de Tunzelman, University College, medalist; T. Hillier, University College; W. B. Mushet, University College; J. N. Winter, Guy's Hospital; J. Ekin, University College; H. Briggs, University College; W. Roberts, University College.

Honours in Botany.—J. W. de Tunzelman, University College, medalist; T. Hillier, University College; J. Ramskill, Guy's Hospital; H. Briggs, University College; J. N. Winter, Guy's Hospital.

Honours in Chemistry.—W. P. Jones, University College, prizeman; F. T. Bond, Queen's College, Birmingham; T. E. B. Brown, Guy's Hospital; S. H. Blackmore, University College; W. Cartell, King's College; J. C. Thorogood, University College, equal; E. Clapton, St. Thomas's Hospital; P. J. Worsley, University College; C. Wolston, Queen's College, Birmingham.

Honours in Botany.—T. E. B. Brown, Guy's Hospital, prizeman; A. W. Bennett, University College; E. Clapton, St. Thomas's Hospital.

Honours in Zoology.—F. T. Bond, Queen's College, Birmingham; C. Wolston, Queen's College, Birmingham; J. H. Thornton, King's College.

TO CORRESPONDENTS.

In consequence of the length of the "Draft Bill" we are obliged to postpone several communications.

Communications have been received from Dr. Merei, Mr. Solomon, Dr. Stanhope Speers, Oculus Apertus, Birmingham Pathological Society, Epidemiological Society, Dr. Oke, Mr. Allsop, Medicus, Dr. Black.

LECTURE ON THE DISEASES OF CHILDREN.

DELIVERED IN THE

Chatham Street School of Medicine, Manchester,

By DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Medicine at Vienna, etc.

LECTURE X.

Special and specific remedies. Hydrochlorate of ammonia, kermes, ammonio-sulphate of copper, cod-liver oil, mercury, iodine, anthelmintics. External remedies.

GENTLEMEN, — *Hydrochlorate of Ammonia* (*Sal ammoniac*) is a remedy used throughout all Germany, Italy, and Hungary, as the most effective in *bronchitis*. An extensive trial and observation has satisfied me as to its good effects, and I recommend it to you with full confidence. I mean in simple cases of *bronchitis*, without acute inflammatory symptoms, (acute pain in the chest along with strong fever, excluding its good effects), without great nervous irritability or spasmodic cough. At any rate, the dose must be smaller in proportion to the greater inflammatory or nervous irritability of the case, the former requiring an addition of nitrate of potash, the latter of tincture of opium, to the solution of the remedy in question. *Pneumonia* is not benefited by it. It acts by promoting resolution by increased action of the mucous membrane, and thus hastens the process of recovery. I prescribe it in the following way:—*R. Aquæ Destil.*, oz. ij.; *Hydrochlor. Ammon.*, gr. viij.—xij.; *Tinct. Opii. Simpl.*, gtt. ij.—iii.; *Extr. Glycir. Liquid*, dr. iss. For children from one to two years old, a teaspoonful every two or three hours. For a child six years old I would prescribe one scruple of the salt to eight ounces of water, and two teaspoonfuls as a single dose.

I beg to remark, that, according to what I expressed in *Lecture VII.*, I do not like to prescribe this mixture to a tender suckling infant, or where gastric disorder is present.

Kermes mineralis, viz., sub-bisulphuretum antimonii, or Plummer's powder, in former times was very much used in *bronchitis* or *pneumonia*. It appears by the inquiries of Professor Skoda of Vienna, confirmed by myself, that it is unworthy of our confidence as a curative power, whilst it easily deranges the stomach of tender infants, and as I have observed a hundred times, it goes out with the feces unaltered.

Ammonio-sulphate of copper I regard as the sovereign remedy of *chorea*. In the records of the Children's Hospital at Pesth, there are 177 cases treated with this substance, 170 of which have been restored to perfect health in the average time of twenty-two days, (the shortest, I think about a fortnight, the longest forty-five days.) The others were cases of the worst kind.

I have seen in many instances, the complication with *chlorosis anæmia*. In this latter case we may properly add to the mixture of ammonio-sulphate of copper, (as I will soon bring it before you,) a proportion of the æthereal tincture of iron previously mentioned.—*R. Aquæ Menth. Pip.*, oz. iv.; *Ammonio-Sulph. Cupri*, gr. viii.; *Tinct. Opii Simpl.*, gtt. viii.—xii.; *Syr. Simpl.*, oz., ss. M.

In this way it will be possible to administer large doses of the remedy, which otherwise easily cause nausea, vomiting, gastric, or intestinal pains, and diarrhoea. The tolerance of it, however, being very different, I almost always commence with one teaspoonful as a single dose, four or six times a day, and increase the quantity gradually, as far as the idiosyncrasy allows it. Many children, from about nine to fourteen years old, could take of this mixture one tablespoonful four or five times a day, or about four to six grains of it, and continue this during some weeks, whilst in powder we scarcely succeed with more than half a grain per dose. When sickness is produced, we cease with it for one day, and then lessen a little the doses.

Cod-liver oil, is the real specific of atrophy without organic destruction, or a high degree of exhaustion: increasing the vegetation, and by it the autoeratic power, we easily conceive how, in many ailments, it can become useful in an indirect way; but directly, it acts only by improving the vegetation which frequently becomes weakened or retarded between the sixth and eighteenth month. If such an individual be affected with any other malady—for instance, with chronic *bronchitis*, or atonic diarrhoea, scrofulous ophthalmia, caries, etc., the basis and commencement of the cure I always effect by cod-liver oil, and in many cases accomplish it without any other assistance.

At Pesth I have prescribed the brown quality of the oil, (got from Norway,) to more than a thousand children in the hospital, and to a greater number besides, in the quantity from two teaspoonfuls to two large tablespoonfuls every day. Sometimes it caused diarrhoea, or increased it if present. This circumstance seldom deterred us from its use, and we succeeded in counteracting it by an occasional dose of Dover's powder, or some aromatic drops, mixed with tincture of opium, but still it is always a disagreeable collateral effect.

The English cod-liver oil, which is white, or nearly so, has the advantage over those yellow and red-brown kinds, of being much less disagreeable to the taste, and, as it seems to me, more easily digestible, and not so irritating to the intestines. Concerning the difference between them, it seems the brown colour depends partly upon the process of fermentation—first, under the action of heat and atmosphere; and, secondly, upon the boiling to which the livers in Norway are afterwards exposed; whilst the English is obtained in the most simple way. As far as I can judge, I do not think the English has less curative power, whilst in all other respects it is decidedly superior to that used in Germany.

Mercury.—Since I regard it as a matter of fact, ascertained by a great number of observations, that frequently repeated moderate or small doses of calomel, are likely

to derange in an insidious way, the state and functions of the mucous membrane of the stomach, to cause in infants or young children even superficial erosions of it, that frequently a more or less conspicuous dyscrasy or cachexy ensues from its use, and finally, that in some cases it has become evident that the vegetation of the child, in particular the process of ossification has been impaired, I must regard it as a mischievous abuse or superficiality, to make use of mercury in children's practice, without necessity and its clear indication. It is not a remedy to be used as a simple and common purgative, and its antiphlogistic and alterative power, the latter in particular, are rather obscure. Nor is it more evident in its action upon the lymphatic or absorbent vessels.

Besides the necessity and efficacy of mercury in all primary, and many secondary, forms of syphilis, I could make clear only the following effects:—Moderate and full doses of calomel produce motions considerably charged with bile, and after its anti-syphilitic quality, in this we find its clearest indications, *i.e.*, to increase the secretion of bile. But as a simple purgative, or as a derivative, intended to exert in this way a beneficial influence upon the inflamed brain or lungs, its action appears to be too slow, and not evidently endowed with a special advantage above liquid purgatives. Its purgative effect is the most retarded in the case of feverish heat, with dryness of the mucous membranes.

As to its direct *antiphlogistic* property, which we attempt to realize by small or moderate doses, in the way of absorption, continued until the mercurial symptoms do appear, this effect, I sincerely confess, is not very clear. We have considered strictly, and subjected to comparative examination, a great number of cases of acute inflammations, partly treated with mercury, (internally and by inunction,) and partly with other remedies, and the conclusion was, that it does not avail against the most acute parenchymatous inflammations of the brain, throat, or lungs, the least of all in infants or young children, in whom these inflammations run with so extreme a rapidity towards their issue, that a treatment by mercury, which acts slowly in proportion to their course, is but a dangerous loss of time. Twelve hours are already a long time in these affections, and it will scarcely be possible in that time to produce mercurial dyscrasy and fever, from which a powerful antiphlogistic effect, so necessary in those affections, might be expected. On the contrary, it seemed to me in a great many cases, that in a slow or a moderate course of serous inflammation—fixed in the pleura, pericardium, abdominal and intestinal peritoneum, or in the articulations—there is some reason for recommending calomel. If, then, transudation has already taken place, (in order to promote absorption,) I advise you, besides the internal use of calomel, to practise at once one generous inunction, (from half a drachm to two drachms,) with the *strong* mercurial ointment, in order to induce *mercurial fever*. Some striking effects of the kind which I have witnessed, have been produced in this way, by reaction and crisis, with profuse perspiration consecutive to it. I have, however, *never observed the*

absorption of the hydrocephalic liquid, (when manifested by the unequivocal symptoms of pressure,) under the use of mercury. In chronic hydrocephalus I found it to be rather mischievous.

My experience speaks decidedly against the use of mercury in infants or children who are weak, cachectic, or much subjected to derangement of the mucous membranes; these are the very *counterindications of mercury*, to which I feel compelled to add a developed scrofulous constitution. It is a deception if one states he has resolved a scrofulous infiltration of the abdominal glands by the use of mercury. These glands are not easily diagnosticated, and the external glands, of a decidedly scrofulous character, have not yielded, as far as I could see, to mercurial treatment.

I content myself with these few remarks upon mercury, to which I could add many others. Children are much less liable to salivation than adult patients, perhaps because their skin is more active, but still I have seen many distressing cases of mercurial cachexy in the early periods of life.

The mercurial disease is, I may say, chemically removeable by a well-managed treatment with iodide of potassium, dissolved, and administered with a large quantity of water.

Iodine, a remedy which, I believe, we may justly call *anti-dyscrasic*, *viz.*, which has the effect of promoting directly the depuration of the organic liquids from some dyscrasic elements. I am far from saying it is a general anti-dyscrasic, nor can I approve of the name of anti-scrofulous, as applied to it, scrofulous "being still a very vague," not to say superficial expression. But I can state the fact, that I have seen *improve*, under its use, *in a proportionally short time*, some hundreds of cases with different complaints, which we usually call scrofulous, and above all, those characterized by impetiginous or eczemato-impetiginous eruptions over the skin, the improvement or cure having been effected in the wards of the children's hospital, *without the influence of change of air or baths*, the usual assistants of antimonial and other remedies, regarded as anti-scrofulous, but which, in the hospital of Pesth, without those assistants, did clearly appear inefficacious. I beg to state, that if remedies would be subjected to similar trials in large hospitals, as we perform them in Pesth, with iodine and some other substances, by and by the number of pharmacological fallacies would become reduced. If any one should ask me, in what manner iodine acts as anti-dyscrasic, I am not perfectly sure how to answer. It acts, evidently, in a stimulant way upon the mucous membranes, the kidneys, and upon the liver. The latter action has not been *duly* noticed, though I can assure you that almost all bilious, or what they call hepatic constitutions, are most disagreeably affected even by small doses of iodine, so that these temperaments are seldom allowed to pass even through a mild course of iodide of potassium. Dyspepsy, for bilious vomiting, is a frequent effect, but I never observed bilious diarrhoea. The most obvious effect of it, however, is to produce irritation in the mucous of the eyes and the

nose connected; in higher degrees, with fever and headache, it acts decidedly upon the urinary apparatus, commonly increasing the secretion of urine, by which more or less of it is again carried out of the body. Its action upon the skin is the latest, and appears as consecutive to its stimulant action upon the mucous membranes. Iodine fever resembles catarrhal fever, and is frequently followed by perspiration. Salivation, and some other effects of it, are less constant and important.

In some individuals, but very seldom in young children, we have observed a slight diminution of the testes; in some ladies the glandula mammaria has been diminished. These effects will sooner happen under long continued small doses than under large ones, when they will excite febrile reaction.

I have observed that the more there was of iodine fever, with consequent crisis, the more evident was the anti-dyscrasic effect of this remedy.

In the clinical case-book of the children's hospital of Pesth there is a considerable number of different affections of bones, of one or more years' standing, in scrofulo-impetiginous children, which, under the phenomena of iodine-reaction, have been cured in the short time of one to three months.

After all that I have seen, it seems to me that *the anti-dyscrasic action of iodine is not a directly chemical one, like that of iron in chlorosis, but appears to depend upon producing a sort of disturbance, the reaction upon which is followed by the curative effect.* From this it seems to follow that whilst in chlorosis we must give iron in frequently-repeated small doses, iodine must be administered in the opposite way. Many cases, however, may be improved or cured without fever. Fever has also its minimum in the body, which is scarcely perceptible.

From the above statements it results that iodine, in order to become a strong curative power, requires a constitution fit for its reception and reaction upon it. Now, full, phlegmatic, or lymphatic constitutions bear it the best, the nervous less, the bilious the least of all. Atrophy and anemia must be removed before we commence with iodine. And when we consider that atrophy is the most direct indication for cod-liver oil, and the most direct counterindication for iodine, it becomes clear that these remedies act in an opposite way, and that cod-liver oil owes not its effects to its infinitesimal part of iodine.

Now, I should feel very glad were I able to point out to you and describe more exactly the cases in which you may expect advantages from iodine. But, without having before us the patients, it is scarcely possible to give you exact directions.

Comparatively full phlegmatic constitutions, affected with eczema-impetiginosum, or even with caries, supported, in general, the strongest iodine treatment, and had the best results of it. This is one of the best results we had in the Children's Hospital with that remedy. On the contrary, prurigo, impetigo, achor, lupus, scrofulous, or tuberculous infiltration of the glands, do not yield to the iodine treatment. Catarrho-scrofulous conjunctivitis also excludes the use of iodine,

because under its action the inflammatory character of this affection almost constantly increases long before an anti-dyscrasic effect could be obtained. On the contrary, I frequently succeeded with it in torpid forms of swelling of the meibomian glands.

If a dyscrasic local affection, which we think proper to be successfully treated with iodine, does occur in an emaciated child, we must, before its use, improve the constitution with cod-liver oil; if the subject is anæmic a course of iron must precede. In children of a nervous temperament, or where we encounter a great disposition to catarrhal irritation of the intestines, we assist the iodine treatment with opium or Dover's powders.

CASE OF

LARGE SINGLE OVARIAN CYST,

TREATED SUCCESSFULLY BY OPERATION.

By D. HOADLEY GABB, Esq., M.R.C.S.E.,
HASTINGS.

THE following case presents many points of interest. At the time the operation was performed, it was considered impossible the woman could long have survived, if the plan of repeatedappings had been adopted. The operation performed was a modification of that proposed by Mr. Bainbrigge and Mr. J. B. Brown, but the external opening was made lower down than has hitherto been attempted, to facilitate the exit of the discharge, and to prevent the bagging of the cyst below the external aperture.

Mrs. L., aged 32 years, tall and slight, has been married seven years, has had three children and aborted twice; has never been strong, though enjoying tolerable health; she suffered occasionally, about ten years ago, much pain in the left side, over the region of the descending colon but does not remember if it was worse during the catamenia; menstruation natural up to her marriage. Had a lingering labour with her first child five years ago, and since then has been more weakly, but had nothing particular to complain of. Was confined again in 1849, and had a good time; she remarked, however, that she did not regain her natural size; health much as usual. Her last child was born in January, 1851; labour natural; after which she so rapidly increased in size that it was necessary to tap her in March, and twelve quarts of clear and highly albuminous fluid were removed; recovered quickly. She again consulted me in October, being much distressed by the reaccumulation of the fluid.

Dr. Tyler Smith saw her on the 27th of that month, and it was agreed if, on a careful examination, all the other internal organs were found to be normal, to perform the operation recorded.

Present State.—Extreme emaciation, the nipple was apparently the only portion of the mammae remaining; thoracic viscera healthy; urine slightly albuminous, probably from the pressure the kidneys were subject to;

externally and per vaginam, the tumour, (in which fluctuation was peculiarly distinct,) occupied the left side. The catamenial discharge (which had just occurred) has been regular since February, when she weaned her infant; she has always remarked that after each period she has got more rapidly larger.

On November 3rd, at eleven A.M., the following operation was performed under the influence of chloroform, and with the assistance of Dr. Tyler Smith, Dr. Steavenson, and Mr. Ranking:—A vertical incision, about three inches long, was made over the lowest portion of the tumour on the left side, a little external to midway between the anterior superior spinous process of the ileum and pubes and extending nearly as low as Poupart's ligament. The integuments and fascia were cut through and the muscle carefully divided, until the cavity of the peritoneum was opened. The sac, (the walls of which were very thin) then came into view, six ligatures were passed through it and the rectus, attaching it closely to that muscle, the fluid was then removed by puncturing the sac with a large trocar, and the operation was concluded by passing a piece of oiled lint into the sac to prevent union and to allow any secretion to escape, and then bringing the edges of the external wound together with sutures, excepting the part left for the plug just mentioned. She bore the operation well.—Nine, P.M. Very comfortable and cheerful; pulse quiet. Gave an anodyne draught.

4th.—Passed a good night; very comfortable; no febrile excitement.

5th.—Going on well.

6th.—So comfortable that I did not think it necessary to remove the dressing.

7th.—Wound healing by first intention; no discharge.

8th.—Passed a bad night; pulse 120; skin hot; troubled much by flatulence and sickness, which she generally suffers from after her confinements; no tenderness of the abdomen on pressure, but a little distended; bowels open; no discharge from the wound.

9th.—Removed the plug out of the sac, and about a pint of clear but offensive serum ran out; wound, excepting the part kept open by the plug, nearly well. The only thing she complains of is the distress from the flatulence, which was removed by compound galbanum pill.

10th.—Slight tenderness on pressure from peritonitis; sickness; pulse 120. Ordered mercury and opium frictions. No discharge from the wound.

11.—Much the same; abdomen tympanitic; sickness still troublesome; no discharge; from the flaccidity of the abdominal parietes the wound is valvular; on removing the dressing an immense quantity of highly-offensive gas escaped, and about a pint of serum with flakes of pus; the silver probe was turned black by the secretion; felt much relieved.

12th.—Comfortable.

14th.—Feels much better; wound discharging freely; fluid of the same character, though less offensive.

16th.—Going on well; tenderness gone; about a teacupful and a half of healthy pus comes away in the twenty-four hours.

From this date she has progressed satisfactorily, the secretion varying from half to a teacupful in the twenty-four hours. She has lost flesh considerably since the operation.

December 31st.—Down stairs; is gaining flesh; weighed eighty-five pounds and a half; discharge about two tablespoonfuls daily.

February 5th.—Has been out for a walk in the garden; weighed eighty-nine pounds and a quarter; about a teaspoonful of discharge.

March 11th.—Sutures not come away; discharge the same; the probe will only pass downwards, backwards, and inwards; the sore is contracted seemingly to a very small size. The catamenia had not appeared since the operation. On examination per vaginam nothing abnormal can be detected. The urine shows no traces of albumen.

22nd.—Weighed ninety-one pounds and three-quarters. Since this date she has steadily continued to improve, and can now take a good walk.

At the request of Dr. Tyler Smith a microscopical examination of the blood, of the fluid which came away when the sac was first opened, and of the fluid which came away at the close of the examination, was made by Dr. Handfield Jones. The following is the microscopical report made by Dr. Handfield Jones:—

1. "The serum was deeply red tinged, contained fewer blood globules than healthy blood, and they were also apparently feebly formed and less coloured than natural; there were many white or lymph globules, and some granular films of fibrin.

2. "The first-drawn fluid contained multitudes of small vesicles, bearing on their walls opaque refracting granules, in number from six to one. I think these were altered blood globules, they were about that size and had much the appearance that blood globules, when roughly treated, sometimes put on; their membrane was often distinct, enclosing a pale fluid. Along with these there were a very few imperfect granule cells and many tablets of cholesterine; the fluid itself was decidedly coagulated by nitric acid, but did not form a very bulky coagulum.

3. "The last-drawn fluid contained a few small flakes of whitish aspect; it was similar to the above, containing altered blood globules. I suppose them to be in abundance, and also cholesterine. The flakes consisted of largish granules apposed together like the bricks in a mosaic pavement; they were perhaps the remains of an altered epithelium. Fat vesicles and cholesterine, were mingled with them.

"All this seems to indicate a low condition of vital power."

April 16th, 1852.—Upwards of five months have now elapsed since the operation described above was performed, and the subject of it has steadily improved during that time. She was not weighed until she began to improve, but though a tall woman, her weight was only, when it was first taken, eighty-five pounds and a half. She had in three months increased five pounds

and a quarter. The comparison between the operation described and tapping, appears favourable to the former. Between the first tapping in March, 1851, and the time when she would have required tapping a second time, viz., in November of the same year, eight months elapsed. Upwards of five months have elapsed since the operation, and her disease has received a most decided check. The probability is, that had she been tapped in November, the sac would ere this have refilled. The loss from suppuration through the opening into the ovary is evidently less than the loss from the flowing of albumen and other elements of the blood into the sac. Under the one the patient steadily proceeded in emaciation; under the other, she has gained flesh and strength. But the future progress of the case will require to be recorded.

REMARKS

ON

SOME POINTS CONNECTED WITH LITHOTOMY.

By ABRAHAM WOOD, Esq., ROCHDALE.

THOUGH without practical value or application, the following fact may, as a curiosity, deserve to be recorded:—

In operating for stone on a boy, ten years of age, who had suffered from the complaint four or five years, I removed with the forceps, first a calculus of the mulberry kind, about the size of a small hazel nut, and then, with the scoop and my fore finger, another of the same character, of an oblong shape, about the thickness of a tobacco pipe, an inch and a half long, and at one end bulging out to a size, nearly equal to the other stone.

It was broken in the extraction close to this bulb, and in examining the broken part, was found to have a common-sized brass pin for its nucleus, the point of the pin lying in the bulbous end of the stone.

The only question of any interest connected with the case, is—How the pin got into the bladder? The boy denies all knowledge whatever of it, and it seems to me most probable that it was swallowed, passed through the stomach and intestinal canal safely, till it arrived in the rectum, where, getting its point entangled in the coats of the bowel, it at length penetrated them, and ultimately, by puncture and progressive absorption, found its way into the bladder. It is not unlikely, from the much greater amount of deposit around the point of the pin, that it entered the bladder a considerable time before the remainder, and this deposit continually accumulating, may possibly have assisted it in making its way, as well as acted as a valve in preventing the escape of urine into the loose textures of the neighbourhood. Another supposition is, that the boy might have passed it as far as he could down the urethra, and that it may in this manner have found its way into the bladder. I presume, however, that were this explanation admitted, it could not possibly have

made the turn under the arch of the pubes, but must have penetrated the side of the urethra, and found its way into the bladder in the manner I have supposed it did from the rectum.

In this case, as well as in one a few weeks before, in a child about three years old, chloroform was administered, and with most satisfactory results. The effect in both instances was complete, and the state of the patients during the operation—in its perfect quiet and stillness—contrasted most favourably with what it would have been without it. In children, especially, whom it is next to impossible to keep from struggling and wriggling about, it is to the operator invaluable, and let us not forget the sufferings it saves our little patients. It may be truly said of it as Portia does of mercy—

"It is twice blessed;

It blesses him that gives, and him that takes."

The only drawback is in its occasionally fatal effects. As far as my recollection serves me in all those cases in which chloroform has proved fatal, it has done so immediately, and never after long-continued inhalation. It seems to be from the sudden shock given to the nervous system, and this is perfectly consistent with the operation of other poisons of a sedative character. Let them be given in small doses at first, and gradually increased, and the patient will be brought to bear with impunity an amount of effect which would, if produced suddenly, be highly dangerous. In Mr. Clement's case at Shrewsbury, in that of a gentleman from the country, under the hands of a dentist in London, and the one at St. Bartholomew's a few weeks since, death was all but instantaneous. In these cases, as well as in many others followed by a like result, there can be no doubt but that every precaution was taken previously, and every cautious means used when symptoms of danger showed themselves. Might it not, therefore, be advisable to administer a mixture of equal parts of pure chloroform and spirits of wine, say for a minute. If this produce the desired amount of insensibility, well and good; if not, as is most probable, another portion of three parts chloroform and one of spirit, for another minute; and if this fail, chloroform in its full strength. By marking the first mixture No. 1, the others Nos. 2 and 3, it would be a very simple proceeding, and with frequently-occurring fatal cases before us, is surely worth a trial. There may be something also in the mode of its administration. I have seen a variety of ingenious contrivances for this purpose, some of which have answered very well, but I have often given it and seen it given by others, poured on a pocket handkerchief, and brought *by degrees* to the patient's mouth and nostrils, and this simple plan has never failed. I like it, inasmuch as it would be next to impossible by it to produce a too sudden effect.

Notwithstanding the great advantages which it affords to an operator, I regret to have to state that in the case I have related the rectum was wounded. I had no idea of it at the time, nor were any of the gentlemen present aware of it, a proof that due care had been taken to empty the bowel; and it was not till three or

four days after that the escape of flatus and fæces through the wound showed unmistakably the mischief which had been done. On referring to the authorities for the best mode of proceeding in such a dilemma, I found them somewhat contradictory. Desault's advice is immediately to divide the rest of the gut down to the anus; and Liston says:—"The earlier the sphincter of the anus is divided, as for the cure of the complete fistula in ano, the better will be the patient's chance of being freed from the annoyance."* On the other hand, Mr. S. Cooper was of opinion that Desault's advice "is entirely erroneous, as numerous instances have proved that the wound may heal up very well without anything of this kind being done. I know of a recent example in which the rectum was wounded with a lithotomy knife; but the cut in the bowel healed up of itself, and never gave any trouble."† Still later writers, Fergusson and Coulson, are wholly silent on the subject. I felt the more anxious, from having been present at an operation on a child of about the same age as my patient, thirty years ago, when the same accident occurred, and the boy for many years suffered much inconvenience from the involuntary escape of fæcal matter from the urethra, and pain and tenesmus from the presence of urine in the rectum.

Finding on the twelfth day that the fæces passed wholly by the wound and by the urethra, and that the wound was assuming an irritable and unhealthy look, I divided the sphincter by passing a bistoury from the nearest point of the wound in the perineum on to my finger in the bowel. The part divided was very slight, the wound into the rectum being near the anus. After this I had no further trouble, the parts healing, and resuming their natural functions very satisfactorily.

Rochdale, April 21, 1852.

THE
LIFE OF THE BLOOD, AS VIEWED IN
THE LIGHT OF POPULAR BELIEF.

FROM

NOTES OF AN INTRODUCTORY LECTURE DELIVERED
BY THE PROFESSOR OF GENERAL PATHOLOGY IN THE
FACULTY OF MEDICINE OF MONTPELLIER.

BY STANHOPE TEMPLEMAN SPEER, M.D.,
CHELTENHAM.

In considering this subject, viz., the blood and the life which animates it, I omit for the present all allusion to any organic demonstration of the fact, dwelling simply upon a proof, always misunderstood, though self-evident and never investigated, albeit peremptory. This proof I shall deduce from popular belief. In medicine it unfortunately happens that this species of evidence is too much neglected; and yet there is no science upon which it is capable of throwing so much

light. On the blood itself volumes have been written; its vitality has been sharply contested; some have gone so far as to deny it *in toto*. Borden was the first to raise his voice against those who harboured the doubt. He alone it was who viewed the question in its true light and in its varied aspects. In treating of it he has left the inimitable impress by which we recognize the master thinker; for no writer upon the blood has exhibited so much genius and so little pretension; and his "*Analyse Médicinale du Sang*" may be considered as a storehouse of ideas, profound, ingenious, and original. But among the proofs adduced by Borden in favour of the "*Life of the Blood*," that which I purpose to consider has been passed over unnoticed. In the investigation, however, of any given subject the science of medicine should accept evidence everywhere and from everything. Is it not the history of human existence? In truth, of all sciences, that of medicine is the most extensive, embracing, as it does, man, in the fullest acceptance of the word; his organization, as well as his capabilities; his development and his necessities; the powers of his mind, and the changes wrought upon him through the influence of external agents; the works he undertakes, the habits he acquires, the passions he exhibits, the manners he adopts, and the belief he entertains.

Now, we know that popular belief has always testified that the blood was at once the receptacle and propagator of the life. I purpose, then, to investigate this belief—to exact an accurate reason for its existence; for if it really exists there must be some grounds for such existence; and the promotion of an instinctive fact to the rank of one supported by mature reasoning, may be truly regarded as the highest mission of the medical philosopher. What, then, is the foundation upon which popular belief usually stands? Under this head we are forced to combine facts bearing no apparent relationship, prejudices and trustworthy opinions, revolting practices and rites (whether civil or religious) eminently useful and worthy of preservation. A people, like one individual, leaves its imprint upon all it touches; its seal is found upon its acts; but as such acts derive their origin from a previous belief, to consult such belief is at once to address ourselves to its very existence. Much difficulty here presents itself in the choice of a plan by which the mass of diversified and incoherent facts bearing upon this subject may be made to assume an uniform but comprehensive whole; the first object being to seize upon that centre or centres around which popular opinions naturally group themselves.

The ties of blood have at all epochs appeared to form the most inevitable and indissoluble of bonds. The idea which they express regulates all the relationships, both of the family circle and of society at large. It is probable, indeed, that in it we may see that secret chain which mysteriously connects together the whole human race. A chain, powerful as it is invisible; attaching without violence, binding without restraining, inculcating union without authority, of which the precepts are impulses, the laws invincible instincts, and which, while

* Practical Surgery, page 517.

† First Lines, Vol. ii, page 355.

existing within and reacting upon us, guides and directs man, independent of voluntary participation.

To imitate these ties of blood, or to draw them more closely together, much pains have ever and anon been taken, and artificial consanguinity, in default of that of nature, has appeared an indissoluble link. A sufficient proof of this assertion is to be found in the history of the passions, those beacons of vitality and self-consciousness.

To the instinct of the passions, then, has the blood at various periods been rendered subservient; and the most horrible denunciations of vengeance on the one hand, and the most tender vows of friendship or love on the other, have often assumed the blood to be the type of the object sworn to.

By a refinement of ferocity Cataline presented to the conspirators a cup filled with blood;—they drank of it, and bound themselves by a fearful oath. But this is no solitary instance; Herodotus, Plato, Tacitus, and Valerius Maximus, in describing the manners of the ancients, attest the frequency of this procedure. Equally terrible is the description given by Æschylus relative to the oath of the seven chiefs before Thebes, when standing around a dying bull they plunge simultaneously their hands in its flowing blood, (emblematical of ebbing life,) and swear by Mars and Bellona to be revenged.

Again, we have an antithesis to the above in the part which the blood is made to perform in the oath of mutual affection taken by the Scythians. The following is their own version, as related by Lucian:—"When (say they) we wish to swear a mutual friendship, we each prick the point of the finger, and receive the blood in the same cup; we then dip the point of our swords into the mixed blood, and carrying to the mouth, suck the precious fluid. This is amongst us the strongest possible mark of inviolable attachment, and the most infallible proof of an intention on either party to shed his last drop of blood for the other."

I might here adduce examples of a similar nature to show that friends, lovers, conspirators, and avengers, have been not unfrequently in the habit of instituting among themselves an indissoluble connection, whether from design or from affection, through the medium of the blood. It constitutes in such cases the link that binds, the sign that recalls, and the symbol that personifies; for the blood is looked upon by many as the life, and as an object of invocation second only to the Deity. They call it to interest them, at one time, as in the case of the ancient Scythians, by mingling together and drinking the blood of friends;—by drinking the blood of an animal, as in Tarquin;—by drinking their own individual blood, as in Poland, when swearing fidelity to a new King;—by sacrificing a victim, in imitation of the sons of Brutus in their oath relative to Tarquin;—by plunging their hands into flowing blood; or by writing in the blood of the individual himself an engagement to remember a promise, or to preserve through life an unalterable affection.

Drink the blood of another!—swear by the blood!—testify by the blood! What does this signify? Regarded

in the light of a symbol, it is to identify one individual with another;—to unite the separate existence of two in one;—to live together the same life. Viewed in a moral light, it indicates a determination to undergo the same misfortunes;—to run the same risks and dangers;—to pursue the same enterprises;—to be united by the same ties of affection. In these mutual and reciprocal engagements the blood serves as a type of the moral tie that is contracted; and just as two individuals, if animated by the same blood, would be liable to the same diseases, so the ancient practice above alluded to produced a species of moral unity, whether of action or sentiment. And in the instinctive performance of the rite a man may have tacitly agreed to more than he would have given utterance to had he known the full import of the symbol.

The sympathy between blood and blood—an idea in its nature both medical and moral—the foundation of the dearest ties, the tenderest affections, was doomed to degenerate, and quackery stepped in to assist, acquitting itself of the task, as usual, marvellously well. Has it not been of old asserted, that individuals might be acted upon at a great distance, provided some of their blood could be procured? Upon this idea was founded the sympathetic powder, (that of Digby, in particular, attaining an astonishing celebrity,) a fragment of cloth, dipped in the blood of a sick man, and sprinkled with this powder, caused him to experience an extreme sensation of cold when the cloth was placed in an ice-house, and a feeling of burning heat when brought near a raging fire. In England this powder turned the heads of multitudes; persons of the highest rank took part in experiments upon it, and the sympathy of the blood appeared to do away with the necessity for scientific research. If sick, the invalid forthwith sent to such and such a one a compress, soaked in his own blood; the physician, on receiving the same, sprinkled over it the necessary remedy, and sympathy achieved the remainder.

The sympathetic lamps mentioned by a Polish naturalist of the 17th century, likewise derived their imaginary prophetic virtues from the same source of vitality. Made with human blood, they constituted a species of vital thermometer, indicating the sadness, the joy, the health, or the disease, even the life or death of the individual, by the feebleness, the brilliancy, or the extinction of their light. Barbarous nations are careless of life, and still more so of the blood which represents it; civilized nations, on the other hand, look upon life and its symbol in a far more sacred light.

The parallel to be drawn from this fact is, in more ways than one, pregnant with contrast; to follow it out may not be amiss. The Scythians drank the blood of their conquered enemies; an inhuman custom, little in accordance with the reputation for virtue and justice, attributed to them by writers posterior to Homer.

Juvenal, in his 15th Satire, relates the narrative of a combat between the inhabitants of two Egyptian towns, and assures us that they took a pleasure in drinking human blood; "for (says he) the last comer,

seeing the bodies of the conquered already devoured, and nothing left for him, in despair gathered up with his fingers the blood that had fallen on the ground, and swallowed it."

Marco Polo, whose credulity upon some points cannot weaken his veracity upon others, says, in speaking of the Chinese, of the province of Koncha, "that in war, after slaying their enemies, they hasten to drink their blood, and then to drown their carcases."

What a contrast here exists between customs of so atrocious a character, and the humanity of modern nations, each, when at war, tending the wounded of the other. But, well may we regard with horror the fact of drinking the blood of an enemy, when its use, as a simple aliment, inspires us with profound disgust, and can be conceived as existing only in legendary fables, or in the history of a madman. Polyphmeus could feed upon the blood of the companions of Ulysses; and Tarran, the more hideous of Polyphagi, upon the blood drawn from diseased individuals, and upon that of dead bodies.

But is the blood noxious; is it a poison, as some assert; or is it harmless? The question assumes now a different aspect. I do not, for instance, believe that the death of Lucan can reasonably be attributed to the blood which his wife caused him to swallow. True, it is said, that the blood of a bull was considered by the ancients as being poisonous. I cannot, however, believe, that it was by this that Themistocles destroyed himself. What would become of the Saminds, who drink that of their reindeers, and attribute to it an immunity from scurvy. Again, the Huns, in the time of Ovid, are reported to have drank the blood of their horses. Voltaire, in order to test the truth of this ancient idea relative to the noxious character of the blood, confesses that on one occasion he ordered a young bull to be bled, and drank a cupful of the blood with impunity. He asserts, moreover, that the peasants of the canton were in the daily habit of using it. What a contrast. While certain animal secretions, milk for example, are considered as nourishment, and taken without preparation, and without repugnance, the blood, similarly taken, inspires disgust; it is, because the blood is the life. Instinct, on the other hand, warns us, that a fluid secretion is a product, but not the life from which it emanates. What a holy horror its mere aspect will often inspire. Did not the bloody robe of Cæsar do more to rouse the spectators than all the eloquence of Antony?

Again, is there to be found a passage of horror in the ancient writers and poets, in which the blood does not figure, or a public disaster of which its real or imaginary appearance has not been a sign? We have but to read the *Æneid* of Virgil, and the history of Titus Livius, to be convinced of the truth which I advance.

Among the prodigies which preceded the second Punic war, Livy reports, that in one locality bloody waters were seen to flow.—Lib. xxij., Chap. 1.

During the same war, rivulets of blood were seen to flow for a whole day in the public forum.—Livy, Book xxvj., Chap. 23.

In the capital, in the forum, drops of blood were seen.—Livy, Book xxxiv., Chap. 45.

Near Mantua, the river Mincio having overflowed its banks, formed a lake, the waters of which were of the colour of blood.—Lib. xxiv., Chap. 10.

Among the prodigies which followed the death of Cæsar, Virgil relates, that springs of blood were seen to flow.—Georgic j., 483.

Quintus Curtius, again, in his description of the prodigies which accompanied the siege of Tyre, lays much stress on the different circumstances under which a supernatural appearance of blood was reported to have taken place. On the side of the Tyrians streams of blood were seen to flow through the flames in which they were forging the necessary weapons of defence; while in the Macedonian army, the soldiers were terrified at the sight of blood flowing from the bread they cut.

If we now turn our attention to the religious rites of Paganism, and compare them with our own, we shall derive a similar confirmation of the popular belief in the vitality of the blood. "It is better," says Bacon, "to ignore the Deity, than to have a low and unworthy opinion of him: the one is indeed an error, but the other is an outrage." "I would rather," says Plutarch, hear it asserted that no Plutarch ever lived than to hear it said that there was a Plutarch who devoured his children at their birth, as the poets say of Saturn."

These words of Bacon and Plutarch show at once the atrocious rites of Pagan religion. The effusion of blood was connected with all their practices and ceremonies. Was it necessary to implore the Gods to appease them, to make a promise, undertake an enterprise, engage in battle, or celebrate a victory? To satisfy the manes of the dead under either of these circumstances, the blood of a victim must needs begin and end the ceremony. So intimately, indeed, was the material idea of the blood, (through their belief in its vitality,) mingled with their religious ceremonies, that during the oblation denominated the *Taurobolus*, and to imbue the act of expiation with all the virtue of this fluid, it was necessary for the priest to expose his forehead, cheeks, lips, nostrils, and hands to the horrible shower of blood, which fell from the flanks of the sacred bull; his clothes were to be soaked, and his body saturated as it were with it. Then, stepping out of the pit in the most hideous condition, and adored as a God, he regained the temple, where his bloody garments were religiously preserved, a certain token of the pardon of the Gods. The walls of Narbonne still retain reminiscences of one of their famous sacrifices made to Cybele, for the cure of an obstinate gout, which tormented Severus during his whole existence. But the priests of Paganism, not content with the blood of animals, inundated their altars with that of man. At one time it was the blood of the dearest relatives, as when the Carthaginians sacrificed their children to Saturn; at another time it was the blood of the purest and fairest of her species; and Iphigenia was led to the sacrificial altar. At another, again, it was the blood of the hated and abhorred enemy, as when the Druids slew the hundredth part of their

prisoners, and Achilles offered twelve Trojans to the manes of Patroclus. But under all circumstances it was blood that was shed—it was life that was sacrificed! Once it had begun to flow on the altars it was no longer possible to arrest it. From the first and most innocent of expiations, the offerings of which consisted simply of bread, milk, wine, and honey, Paganism proceeded to the immolation of animals, then of children, and then of man, until this barbarous custom was arrested by the glorious advent of Christianity.

The religion of the ancients sanctioned mortal combats between gladiators: Christianity appears, and its first veto is upon these sanguinary conflicts. At a later period, tournaments are forbidden upon the same principle. Later still she forbids priests the innocent pleasures of the chase, and alike prevents physicians, who were then priests, from exercising surgery, all with a view to avoid the sight of blood; for, says the councils, the Church holds it in abhorrence.

This horror of blood, this respect for human life, is alone sufficient to separate Christianity from other forms of worship; and this single idea places the widest interval between the world of Paganism and that of Christianity.

We now come to a species of testimony still more decisive. I deduce this from the fact, that, wherever science, on the one hand, or ignorant prejudice on the other, has endeavoured to purify life, to prolong it, to take it as a witness, to remove it from bodies which enjoy it, or to diminish its energy, it has been through the blood that the attempt has been made.

In a religious light, spiritual purification has always gone hand in hand with corporeal cleansing, and in this last point of view, the blood, as the receptacle of the life, has attracted the attention of the chief of all creeds. I shall not much insist upon proofs of this nature, generally, indeed, well known, I content myself with saying that a vague but instinctive presentiment appears to have taught the ancients, that the life is in the blood.

Moses says in *Livit. 17, v. 11.* “*Anima omnis carnis in sanguine est;*” and if the Almighty forbids his people the blood of certain animals, it is because, as the sacred text says,—“*Eorum anima, in sanguine est.*” Their life is in their blood. The soul is not here confounded with the life, it is expressly said:—“The soul of the flesh, the soul of the body—*alias* the life—the existence, and not the soul of the intelligence. The ancients admitted three species of existence:—the intellectual, the animal, the vegetative. Of these three, the “*anima carnis*” of the scriptures, could be no other than that denominated by Hoffman, (“*l’ami medecale,*”) or what we should now designate as the vital force, a power unconsciously regulating the functions of the body, and superintending all those acts which do not emanate from the intelligence or the will. In this sense alone can we interpret the text above mentioned; and moreover, such is the only interpretation which can legitimately be placed upon similar expressions occurring in the ancient writers, whose metaphorical language often bears a considerable analogy with that of the Hebrew legis-

lator. In no other way, again, can we interpret Virgil, when speaking of those who perish from loss of blood. He says:—“*Purpuream vomit ipse animam.*”

[To be continued]

Hospital Reports.

MANCHESTER ROYAL INFIRMARY.

CASES

Reported under the terms proposed by the Association.

By MEDICUS.

Calculus Vesicæ: Lithotritry.

DANIEL PLUMMER, aged 50, engraver to calico printers, was admitted into the Manchester Royal Infirmary, October 7th, 1851. He states that his family are healthy, not suffering from urinary affections. His habits have been rather intemperate, until about seven years ago; during the latter period he has been tolerably sober. His habits are active; has enjoyed good health, and always had plenty of food. About five years ago, symptoms of calculus began to make their appearance. Pain in the loins and abdomen; pain on going to stool; micturition frequent, painful, and at times the flow was stopped suddenly; urine loaded with mucus and tinged with blood, at times small bits of gravel passed. When admitted the symptoms were still more marked. Micturition painful and frequent, often every five or ten minutes, which disturbs his rest at night; urine scanty, light coloured, and acid; pain in passing his motions; bowels constipated; skin dry; pulse regular; tongue rather coated. His health is suffering, and he complains of debility and want of appetite. On passing the sound a stone was at once discovered, which was supposed to be small and soft. He was ordered:—*Extra diet. R. Decoct. Perciræ Bravæ, oz. viij.; Liq. Potassæ, dr. iss.; Tinct. Hyoscy., dr. iij. M. Cap., oz. j., quartis horis. Ol. Ricini, pro re natâ, Tinct. Opii, m. xl., omni nocte horâ somni sumend.*

Lithotritry having been determined on, the lithotrite was ordered to be passed twice a week. At first it caused some pain, but this speedily subsided as he became accustomed to the operation. Under the above treatment he improved very much; was able to keep his water for two hours at a time, and he was sometimes not disturbed in the night at all. At the latter part of October his health seemed to be suffering from the air of the hospital, and he was sent out for a fortnight.

November 14th.—Readmitted.

15th.—It was determined to crush the calculus. He was brought into the operating theatre, laid on a low couch, knees bent and kept separate, hips raised, and body well clothed. About ten fluid ounces of water, lukewarm, were slowly injected, causing little or no pain,

and the catheter being withdrawn, the lithotrite was passed, a stone speedily caught, and as easily crushed three times, without the aid of the screw, pressure being made on the anterior blade with the thumb. When the instrument was withdrawn, a quantity of triple phosphate calculus was found between the blades. The patient was put to bed, and ordered two ounces of Port wine in hot water immediately. Infus. Lini ad libitum.

Eight, P.M.—No shivering; slight pain on pressure on abdomen; has passed a quantity of urine, containing much mucus and some fragments of calculus.—R. Pulv. Doveri., gr. x., horâ somni sumend.

16th.—Slept well; has passed a large quantity of mucus and more fragments, which weighed, when dry, half a drachm; bowels not moved; pulse rather quick; no pain.—R. Ol. Ricini., oz. j., statim sumend.

18th.—Going on well; slight pain in making water. No more fragments have passed,

20th.—Has no pain; tongue clean; pulse 68; bowels regular. No more fragments come away.

22nd.—He was again operated upon. The stone was crushed four times. He complained of more pain than at the former operation. Ordered wine and Infus. Lini as before.

Eight, P.M.—Has passed a quantity of urine, mucus, and large fragments, one particularly so. Pulse quick, restless, and has had some rigors.—R. Spt. Ætheris Nitr., dr. ss.; Tinct. Opii., m. xl.; Aq. Camphor., oz. iss.. M. Fiat haust. statim sumendus.

23rd.—Slept well; has had no more shivering; has passed more fragments; feels comfortable; pulse quiet.

24th.—Complains of pain in passing water; more fragments have come away; pulse quick; tongue furred; slight tenderness of abdomen.—Rept. haust. horâ somni, and in the morning begin the following mixture:—R. Decoct. Pereiræ Bravæ., oz. viij.; Acid. Hydrochloric Dil., m. lxxx.; Tinct. Hyoscy., dr. ij. M. Oz. j. ter die sumend.

26th.—Much relieved by remedies; urine passed with much less pain; sleeps well; appetite only poor; pulse quiet and regular; no tenderness; more fragments have come away.

28th.—Last night a large fragment got impacted in the urethra, when some warm water having been injected, it was removed by a bent probe. A No. 6 sound then passed easily into the bladder.

From this time he rapidly improved; a few small portions of stone passed, and in two or three weeks he was discharged, free from all symptoms of stone.

This case presents features of interest, inasmuch as it was successful on a stone of considerable size, which had existed a great length of time, where it was, therefore, probable that the bladder might be diseased, and at an age when the prostate gland is often enlarged.

Compound Fracture of Both Arms; Double Amputation.

SQUIRE SANDFORD, aged 15, factory operative, of Ratcliffe, was admitted into the Manchester Royal

Infirmary March 3rd, 1852. When examined it was found that he had a compound fracture of both arms, with extensive laceration, so that the integument and muscles were stripped off from the bones, even to the last phalanx of the fingers. He had been brought from Ratcliffe, a distance of some miles, where the accident had been caused by his being carried round a shaft by a strap several times. When he arrived at Manchester, he had rallied considerably, and *complained of pain* in the injured part. His pulse was tolerable. He was taken into the operating theatre, and both arms removed below the elbow whilst he was under the influence of chloroform. The stumps were dressed with wet lint, and he was removed to bed. An hour after the operation he was very comfortable, and his pulse better than before it.

March 4th.—He had some sleep during the night; tongue moist; complains of no pain; has passed urine freely, and bowels been opened once.

6th.—He has continued tolerably well; had a good night's sleep last night; tongue moist; bowels open; free from pain.

8th.—The stumps feel hard and uncomfortable, and in order that the dressings might be removed easily, water-dressing was ordered to be put over them.

9th.—The dressings were removed, and the stumps are uniting beautifully. Ordered to be dressed with water-dressing every day.

From this time he improved rapidly, and was made an out-patient April 10th, 1852, with the stumps very nearly healed.

I am induced to report this case, from its being one illustrating the question of primary and also double amputation. It was recommended formerly that when a double amputation is necessary, they should be done at the same moment, two surgeons operating, that the system might only receive one shock. The introduction of chloroform has obviated the necessity for such a proceeding, and it is remarkable how little the boy suffered from shock. I would just notice that there was here the best warrant for operating, according to Guthrie and other eminent surgeons, viz., "pain in the injured part."

Simple Fracture of the Thigh, and Compound Fracture of the Leg.

JAMES GREAVES, aged 14, of Manchester, was admitted into the Manchester Royal Infirmary, February 10th, 1852, having been run over by an omnibus. On examination there was found a simple fracture of the right thigh in its upper-third, and a compound fracture in the tibia and fibula of the left leg. The wound communicating with the fracture was about two inches long, and after the removal of a sharp splinter of bone, could be easily brought together. It was situated on the front aspect of the leg. The thigh was put up on the long straight splint, the leg on two side-leg splints, the wound being brought into close apposition, and closed by a pad of dry lint dipped in blood, and an

aperture left in the bandaging over the situation of the injury.

February 11th.—He is feverish; tongue dry; pulse quick; has some pain in the leg, and has had a bad night; bowels confined. A purgative draught was ordered immediately, and then to take an ounce of the following mixture every four hours:—R. Mist. Ammon. Acet., oz. viij.; Morph. Acet., gr. j.; Spt. Æth. Nitr., dr. ij. M. Fiat mist.

13th.—He is better, but the bowels were not very freely opened; the tongue is furred; pulse quick; little pain in leg; urine passes freely. R. Hydrarg. cum Creta, gr. iij.; Pulv. Rhei, gr. v. M. Fiat pulv statim sumendus.

15th.—He is much better; tongue cleaner; pulse quiet; bowels regular; very little pain in the leg; has had a good night, and the limbs are both quite straight.

17th.—He continues to progress favourably.

19th.—His bowels being again confined, he was ordered to have the powder repeated; he was free from fever; tongue clean; no pain; the wound is still closed by the pad, and there is no suppuration going on at all.

From this time there was nothing worthy of daily note, suffice it to say that he improved rapidly, that the pad was never removed from the wound, that it separated after some time, and the wound was quite healed. He was discharged cured March 14th, 1852.

I have thought this case worthy of report, as showing the success of the above treatment, even in cases where it could not be expected. Little constitutional irritation was remarkable, and the cure speedy and complete.

Dislocation of the Humerus, with Fracture.

JEREMIAH LINDLEY, ostler, aged 58, Harpurhey, was admitted into the Manchester Royal Infirmary, March 30, 1852, having fallen from a considerable height, and pitched on the shoulder.

On examination there was found to be excessive tumefaction of the soft parts about the shoulder; a flattening in the situation of the deltoid muscle; the head of the bone was thought to be felt dislocated forwards, and crepitus could be distinctly perceived. After a trial at reduction, which was unsuccessful, it was thought better to wait until the swelling had in some measure subsided. Ordered Cataplasma Lini. et Haust. Pergans, oz. ij., statim sumendus.

March 31st.—The bowels were opened by the draught; the shoulder is very much swollen; he has great pain in it; pulse rapid.

Eight, P.M.—Traumatic delirium came on, and he was very violent. Capt. Tinct. Opil., m. lx. Mist. Camph., oz. ij.; statim. et Tinct. Opil., m. xx., quartâ quaque horâ si opus sit.

April 1st.—The delirium is better; he had some sleep in the night; the pain and swelling in the shoulder quite as great as ever; perhaps from his having knocked about so when delirious.

2nd.—The swelling in the shoulder is not so great, but he is feverish, and the bowels confined. Ordered Haust. pergans, oz. ij., statim sumendus.

Eight, P.M.—During the evening the delirium has returned. Rept. Haust. Anodynus.—R. Tinct. Opil., dr. iij.; Spt. Ætheris. Nitr., dr. iv.; Aq. Cinnam., oz., viij., Capt. oz. j. quartâ quaque horâ.

3rd.—He is much quieter, but the way in which he has knocked about has made the shoulder worse. To take mixture as before.

4th.—He has passed a tolerable night, and feels better this morning, and the shoulder is better. In the afternoon he suddenly vomited a quantity of blood of a bright colour. Ordered Ruspini's styptic, and ice to swallow. The vomiting of blood continued, and he died early on the morning of the 5th. The quantity of blood vomited was very great.

Post-mortem.—The stomach was found in a state of follicular ulceration, one ulcer having opened a vessel, the aperture in which was distinctly perceptible. The rest of the viscera healthy. On examining the shoulder there was found dislocation of the head of the humerus into the substance of the pectoral muscle, fracture through the *anatomical* neck of the humerus, and a second fracture just below the *surgical* neck.

Fracture of the Sternum.

GEORGE HIRST, labourer, Mosley, was admitted into the Manchester Royal Infirmary, April 7th, 1852, having fallen from a building five stories in height.

On examination he was found to have received a compound comminuted fracture of the right leg, dislocation of the left ankle, with Pott's fracture of the fibula, and fracture of the sternum rather high up. He was in a state of great collapse, from which, notwithstanding all the treatment adopted, he never rallied, but died in about four hours.

Post-mortem.—The sternum was found fractured obliquely just below the cartilage of the second rib, and the internal mammary artery torn across. There was a slight effusion of blood from this source. The fracture of the right leg was found to be very much comminuted, and the fibula in the left leg very much split and irregularly fractured. The viscera were healthy.

I am induced to report these two cases from their great rarity. Fracture through the anatomical neck of the humerus is a very rare accident, and is not often verified by a *post-mortem* examination. The follicular ulceration one would think, had existed before, and his death from this cause rather a coincidence than having anything to do with the fracture.

QUEEN'S HOSPITAL, BIRMINGHAM.

CASES

Reported under the terms proposed by the Association.

BY SCRIBATOR.

Ovarian Disease; Paracentesis performed twice; Death; Post-mortem examination.

MARY TATE, aged 46, married several years. No children. This patient was admitted into the Queen's Hospital under the care of Dr. B. Davies, who afterwards transferred her to Mr. Sands Cox, for the benefit of surgical treatment. Upon admission, the following account of the case was elicited.

The patient has been ailing five months, first symptoms consisting of pain, at times acute, in the right iliac region; soon after which a swelling, the size of an egg, was discovered in that part. This swelling increased gradually, and has continued to do so until the present time, notwithstanding medical treatment has been resorted to.

On admission there was some oedema pedum, which had been present about three weeks, and with the swelling of the abdomen formed the chief subject of complaint. She measured forty inches round the abdomen, which was without tenderness, but in the middle and right side the fingers seemed to impinge on a solid body, after affording a sensation of displacement of fluid material. The hypochondria and lumbar regions sounded dull on percussion, and afforded no other evidence. The general health was tolerably good, the bowels inclined to costiveness, and the heart's action, although vehement, without abnormal sound. Urine scanty and containing lithates. Menstruation regular and natural, and uterus high up. Breathing slightly oppressed. Countenance somewhat pale.

She was under medical treatment for some months, sometimes measuring a few inches less, and sometimes a few inches more, until November 12th, on which date the abdomen measured forty-six inches and a half, and fluctuation was apparent to the touch, the tumour before mentioned still being felt on attentive manipulation. Mr. Cox, on the above date, performed paracentesis abdominis in the usual manner, and forty pounds of fluid were drawn off by the cannula. The major part was of a yellowish serous character, of specific gravity 1014. The latter portion drawn off was of a much thicker consistence, and its exit was interfered with by the tumour pressing on the cannula, and therefore requiring to be pushed back with a female catheter. The tumour was found of the size anticipated—as large as a man's head, and smooth and uniform to the touch. The probe in the cannula, however, experienced a very firm resistance, as from a solid body, and its point seemed to grate over a roughness as of firm fibrin or scirrhous. During the operation she complained much of pain at the epigastrium, “as if it was being crushed,” and at one time there was some diaphragmatic spasm, with difficulty of breathing. After the operation and

bandaging were completed, she felt tolerably comfortable, and the pulse was calm, although somewhat weak. She had no medicine.

Nov. 15th.—Has felt low at times, but abdomen is tolerably free from tenderness. Nil.

19th.—Reports herself much better.

22nd.—Bowels disposed to be confined; feels tolerably well. Discharged relieved. To take castor oil occasionally.

Five weeks afterwards she was again admitted, the fluid having again accumulated to as great an extent as before. It was, therefore, again determined to relieve her by tapping; and about the same quantity of fluid material was again taken away, having the same characteristics as that first withdrawn. She went on well until the sixth day after the operation, when she was suddenly seized with symptoms of collapse, attended by feeling of great depression at the præcordium. Stimulants were vigorously administered, but in spite of such agents the extremities became cold, and she died in a few hours without any attempt at reaction having been set up.

Post-mortem.—When the cavity of the abdomen was opened, a large tumour almost twice the size of a man's head was found, connected with the right ovary. This was contained in one or two still larger cysts, which had contained the fluid matter withdrawn by the cannula; and the external surfaces had contracted extensive adhesions, both with the different intestinal coils and also with the internal surface of the peritoneum. Upon making a section of the tumour, that also was found to be composed of a multitude of cysts, one within the other, and containing fluid of varied thickness, from the consistence of pus to that of clear water. The colour also of these contents was as varied as the consistence; and the coats of the different cysts were scarcely two of the same degree of thickness, some being thin as tissue paper, others as hard and firm as chamois leather; all, however, contained a large quantity of albumen. The diaphragm seemed pushed up, so that the thoracic space was encroached upon; but its contents were healthy, as also were the viscera of the abdomen and pelvis. The intestines, however, were pale, and of small calibre. The brain was healthy, but its ventricles contained much fluid.

The diagnosis, treatment, and pathology of ovarian tumours, are undoubtedly matters of the greatest interest, and deserving the strictest investigation at the hands of the medical profession. At the present time the diagnosis is tolerably certain, and the pathology is comparatively well understood, but concerning the treatment there yet remains much difference of opinion, notwithstanding the labours of Phillips, Lee, Southam, Bird, Simpson, Hughes, and others, have of late thrown much light on the subject. The progress of the disease is comparatively free from pain, occasional attacks of inflammation taking place, giving rise to adhesions, and rendering operative interference more dangerous and uncertain. This was the case as regards the history of the patient reported, the occasional attacks of acute

pain in the right iliac region being due to such cause. It is now known that frequently ovarian disease assumes a malignant character, which of course only adds to the fatality of the affection, but whether malignant or not in its nature, it is allowed on all hands for the most part to lead steadily to an untoward result; and medicine having little or no control over its progress, it hence becomes a question if the surgeon, by his skill, may be able to cure, or avert for a time, the fatal termination.

For these purposes several operations have been devised, which may, with propriety, be divided into the palliative and radical methods of treatment; by the latter term it being understood that a permanent cure is the intention of the operator. The operations devised vary much in magnitude, and the palliative, or paracentesis abdominis, is generally considered a trivial matter, but it is not without danger; and some cautions are required both after and during its performance. The application of appropriate pressure, as first advocated by Dr. Mead, not being forgotten; as syncope, with hæmorrhage, and peritoneal inflammation, are complications which may occur, thus showing that the operation is not without at least some points of danger. That it may, however, be performed with impunity, is evident, from the recorded cases where it has been resorted to many times in the same individual, one patient having been tapped eighty, another 240,* and another 128 times.†

It is, however, but a palliative treatment, although it occasionally prolongs life for an indefinite period. The writer is aware of one case of ovarian disease, where tapping was performed some five years back, and has since been once again resorted to, the patient remaining since the last operation, till the present time, in a very comfortable state, although a slow accumulation is evidently again taking place. The majority, however, do not survive tapping more than three or four years.

"Upon the whole, (says Dr. Watson,) it may be stated of this operation, as applied to ovarian dropsy,—1st, that when essential to the comfort and continued existence of the patient, it brings sensible relief to her distress, and often materially prolongs her life; 2nd, that when it is performed under less pressing circumstances, it tends to shorten the patient's days." And to prove that the operation should not be resorted to simply in consequence of slight inconvenience, caused by bulk or weight, the same author brings forward a case where the patient lived, with such a tumour, between twenty and thirty years, and not "without enjoying life."

Regarding the radical or major operations, some cases have been reported which have terminated successfully, and the success is said to bear a proportion as of one to three and a half. The first operation of this kind was performed by an American, named McDougall, and successful cases have been recorded by Dr. Bird, Mr. Phillips, and Mr. Clay, &c. Mr. Clay having operated as many as fifty times. Mr. Cornish of the Taunton and Somerset

Hospital, and Mr. J. Beales, of Halesworth,* have each recorded latterly successful cases in the pages of the *Provincial Medical and Surgical Journal*. Still, notwithstanding these instances, the operation is one which requires the greatest consideration, care, foresight and skill; and when we remember that not only has the peritoneum been opened, and the operation remained incomplete, from the extensive adhesions present, but also that "patients have been operated upon in whom no tumour existed," and this, by competent and experienced men, it perhaps may be pardoned if the bias remain in favour of the palliative and certainly less dangerous operation, of paracentesis abdominis. At the Bath and Bristol meeting of the Provincial Medical and Surgical Association, December 19th, 1850, Mr. Grant Wilson read some cases of ovarian dropsy, and detailed "a mode of operating which differs in some important respects from any hitherto described." The first case reported by Mr. Wilson had been tapped twice before the radical treatment was employed, which consisted in the application of potassa fusa below the umbilicus, and the injection of iodine into the sac; and although the case terminated favourably, Mr. Wilson, with magnanimity, adds, "though I am justified in calling it a cure, I should scarcely be disposed, except under peculiar circumstances, to recommend a repetition of the treatment, as it was not entirely free from risk, and the progress of the case was very slow." The second and third cases were, however, perfectly successful, and the principles laid down by the author for the proper performance of his operation, are:—

"1st. To make as small an incision as possible.

"2nd. To draw out only as much of the cyst as could be extracted readily, and without displacement of the other contents of the abdomen.

"3rd. To endeavour to keep the wound always filled with the cyst, so that neither air nor fluid should be admitted into the cavity of the abdomen.

"4th. To cut off the cyst not close to the wound, but from one and a half to two inches behind it, so that when the portion of cyst has been removed, the cut margins could be carefully examined, and the vessels secured.

"5th. To secure each vessel on the cut margin of the cyst separately by a fine silk, and to cut off both ends close, so as to have no ligature hanging from the wound.

"6th. To close the external wound as quickly as possible."

This procedure, as may be seen, differs in several essential points; and in the writer's opinion is preferable to the operation called *minor*, proposed by Dr. W. Hunter and performed by Dr. Jeafferson, and since adopted by other surgeons.

Thus the chief operations for the cure or relief of ovarian disease are uncertain in their results, and somewhat dangerous in the performance; and it seems proper that while they are not wholly condemned they should only be regarded as a *dernier resort*, and that only in

* Watson's Practice of Physic, p. 331.

† Dublin Hospital Gazette, p. 187, 1846.

* *Provincial Medical and Surgical Journal*, October 30, 1850, p. 598; July 23, 1851, p. 397.

cases of a favourable nature; but when it is considered that no one would probably submit to the operation in the very early stage of the disease, and that in the latter stages adhesions, &c., prevent the proceeding, the number of cases where it is advisable becomes very small indeed.

Acupuncture has been recommended, and in some cases performed, for the relief of ovarian dropsy, in the hope that the fluid might be absorbed on its escape into the abdominal cellular tissue; but from the number of punctures necessary to effect this result, and from the frequency of erysipelatous action following such punctures, the operation is no longer entertained, and has now fallen into deserved disuse. Puncture also of the tumour through the uterus or vagina has also been recommended, but the cases have terminated fatally; and, so far as the writer is aware, the same may be said of evacuation of the contents through the fallopian tubes, lately mentioned by Dr. Hughes Bennet in the *Edinburgh Monthly Journal*; although there is no doubt that ovarian tumours have disappeared spontaneously, probably finding the passage through the ducts before mentioned.

In the case reported in this paper no other treatment than that of paracentesis could have been adopted. From the examination during life, adhesions were evidently extensive; and the tapping was only had recourse to after varieties of medicines had been tried, and when the distress caused by the bulk of the tumour was more than could conveniently be borne. The *post-mortem* examination fully bore out the propriety of this line of conduct, as the extensive adhesions which were then seen to exist would have rendered any other operative interference next to impossible.

Provincial Medical & Surgical Journal.

WEDNESDAY, MAY 26, 1852.

It has for some time been in contemplation to introduce regulations, in virtue of which all *bonâ fide* physicians, from whatever University they may derive their diploma, at present actually in practice as such, may be collected beneath the wings of the London Royal College of Physicians. The draught of a Charter to effect this purpose has at length been put forth, and we think it incumbent upon us to lose no time in laying it before the large body of provincial physicians, as parties who are especially interested in it. Of the several clauses we have little to say; but we must think that, considering the large number of individuals who will, ere it can become law, be compelled to join the College, a lower fee than £15. 15s. might have sufficed, as this, together with the Government stamp, will amount to

something considerable. We are also disposed to ask what precautions the authorities will take to ensure the honesty and respectability of those who seek to join the College. Will every one who can shew a piece of parchment be allowed to parade himself as a member of the Royal College, whatever may be his line of practice? Will the globulists, *et hoc genus omne*, be allowed to enrol themselves? Respectable physicians have a right to know this ere they commit themselves by the sanctioning of a plan which otherwise seems calculated to work great good.

The following abstract, which we borrow from a contemporary, gives a succinct view of the intentions of the Charter:—

The preamble repeals former Acts and Charters, except such portions of the 32nd of Henry VIII. as may be consistent with the proposed Charter.

Clause I. Alters the title from Royal College of Physicians of London, to Royal College of Physicians of England.

II. Provides for constitution of College, viz., fellows and members, including President and Council, four Vice-presidents, four censors, a treasurer, and a registrar.

III. All present licentiates to be members.

IV. All present extra-licentiates to be members, on presenting satisfactory testimonials of character, and on paying a fee of £15. 15s., exclusive of stamp-duty.

V. All persons, graduates of recognised Universities, practising as physicians, (and who have practised for three months previous to granting of Charter,) and who do not practise pharmacy, to be members, without examination, on presenting testimonials and paying fees, any time within twelve months after granting of Charter.

VI. Graduates of recognised Universities, aged 26, to be subsequently admitted as members by examination.

VII. The present Fellows to continue Fellows.

VIII.—Any member, of four years' standing, to be admitted a Fellow by examination.

IX. During twelve months after granting of Charter the Council may nominate, at discretion, any number of present members, without regard to the date of membership, to be Fellows.

X. After the twelve months aforesaid, the Council may yearly nominate, at discretion, members of four years' standing to be Fellows.

XI. Fellows to be elected by ballot annually, on June 25.

XII. Provides for the expulsion of Fellows or members guilty of fraud, or imposition, or of violating by-laws, &c.

XIII. The Presidentship to be annual; the present President to continue to be President till the day next after Palm Sunday, and then to be capable of re-election.

XIV. On said day, the Council propose a Fellow from among the first fifty as President, to be elected by ballot, by a majority of the Fellows; if not received by the Fellows, a second nominee to be proposed by the Council from among the first fifty, and so on.

XV. On death of President, a new President to be at once elected, a Vice-President officiating *pro tempore*.

XVI. The President to appoint four Fellows from among the first fifty as Vice-Presidents.

XVII. On death of President, the Vice-Presidents cease to be Vice-Presidents.

XVIII. The Council to be composed of sixteen Fellows.

XIX. Four of the Council to retire annually, and to be incapable of re-election for one year.

XX. The Council to be elected by the Fellows, in a method provided by the by-laws.

XXI. The President, Censors, and Treasurer, to be *ex officio* members of Council.

XXII. The Censors to be annually elected.

XXIII. The Council to nominate Censors, to be proposed to the Fellows, to be elected by ballot. If any proposed Censor be not elected, another Fellow to be proposed by the Council, etc.

XXIV. On death of Censor, a new Censor to be at once elected.

XXV. Treasurer to be annually elected, and to be eligible for re-election.

XXVI. In case of death of Treasurer, a new one to be at once elected.

XXVII. The Registrar to be annually elected, and to be proposed by the President to the Fellows. The retiring Registrar to be capable of re-election.

XXVIII. A new Registrar to be at once appointed in case of death.

XXIX. All the officers retain office during the day on which their successors are elected.

XXX. The days of election may be changed by by-law.

XXXI. No proxies allowed.

Reviews.

Sketches of Brazil; including New Views on Tropical and European Fever; with Remarks on a Premature Decay of the System incident to Europeans on their Return from Hot Climates. By ROBERT DUNDAS, M.D., Physician to the Northern Hospital, Liverpool; formerly Acting Surgeon to H. M. 60th Regiment; and for twenty-three years Medical Superintendent of the British Hospital, Bahia. London: Churchill, 1852. pp. 449.

THIS interesting work consists of an introductory chapter, wherein the various authors on the subject of fever are noticed and commented on; of two "Lectures on the Premature Decay of the System in Europeans returning from the Tropics;" of five "Lectures on the Pathology, Causes, and Treatment of Fever;" of a "Lecture on the Hygienic Conditions of, and the Diseases Prevalent in, Brazil;" of one "On the State of the Medical Profession in Brazil;" and of an appendix, consisting of two papers, on the

"Treatment of Fever by Large Doses of Quinine," (to which system the author gives the name of *cinchonism*;) published respectively in the *Medical Times* and *London Journal of Medicine*. The lectures were delivered in the Liverpool Northern Hospital, in the early part of 1851.

In Lectures I. and II. Dr. Dundas makes some valuable observations on the premature "break-up" of the system in Europeans who have returned from the tropics; but we must content ourselves with advising our readers to peruse them for themselves.

The most novel part of the work is that which relates to fever, and here Dr. Dundas boldly declares himself an opponent of those doctrines which have been handed down to us with the sanction of great names.

The doctrine that marsh poison is the sole generative cause of certain forms of fever, has been commonly attributed to Lancisi. Dr. Dundas, however, points out that Lancisi has been *quoted*, not *read*. He has never met with any individual who has perused the works of the Italian physician; and, after some trouble in discovering where they existed, has, from a perusal of a copy in the Royal College of Surgeons of England, arrived at the conclusion that the "recorded doctrines of Lancisi are widely at variance with those so universally and erroneously attributed to him, especially by the moderns." This subject is discussed in Lecture III.

Lecture IV. is devoted to a consideration of the prevailing doctrines on malarious fevers. Dr. Dundas here combats the doctrine that periodicity is a distinctive character of fevers which originate in marsh poison; and also furnishes us with an *olla podrida* of the opinions of those authors who have written on the nature and properties of marsh poison. A most heterogeneous mass it certainly is.

In Lecture V. Dr. Dundas submits to us the grounds on which he was led to reject the doctrine of marsh miasm. The city of Bahia, where he was Medical Superintendent of the British Hospital for twenty-three years, contains,—

"In almost unexampled abundance, all those physical conditions which are deemed, by the unanimous consent of physicians, to constitute the elements essential for the generation of the most deadly scourges of humanity—epidemic and endemic diseases. I may further add, that I have myself, within the last twenty years, witnessed the city exposed, on three several occasions, to the combined horrors of siege and famine, with all their revolting contingencies; yet, notwith-

standing this appalling combination of physical, moral, and social evils, Bahia continued healthy."—pp. 203—4.

The salubrity of Bahia is mainly attributed by the author to the equality in the temperature between the day and night, the extreme daily range being about six degrees; the highest range of the thermometer in the upper city generally does not exceeds $82\frac{2}{3}^{\circ}$ Fahrenheit in the summer, and the lowest in winter is 72° .

From various cases which came under his notice, Dr. Dundas was led to conclude that intermittent fever—

"Did not arise from marsh poison, but sprang directly from imprudent or too early exposure to a strong current of cool sea-air, loaded with moisture, while the system was under the debilitating influence of previous exhaustion or disease."—p. 232.

In Lecture VI. the hygienic condition of some of the districts in the neighbourhood of Bahia is treated of, and the doctrine of malaria is again vigorously attacked, but we must pass on to make a few extracts from the next lecture, in which a subject of great practical importance is treated of.

In Lecture VII. Dr. Dundas expounds his views on the treatment of intermittent, remittent, and continued fever, by large and frequently-repeated doses of quinine. His treatment of typhus fever is that which has attracted most attention. He says:—

"Acting on my conviction of the essential identity of the remittent and intermittent fever of the tropics with the typhus fever of Europe, and aware of the specific action of quinine in every stage of the former diseases, I have resorted to its administration in the ordinary typhus of this country, in all its stages, and commonly with the happiest results. * * * In typhus, as in the remittent of hot climates, the treatment by quinine will be successful in proportion to its early administration. The doses also, as in the tropical fevers, should be large, ten or twelve grains, and repeated at intervals not exceeding two hours. Three or four doses will, in most cases, be sufficient to produce its specific influence on the nervous system, which is commonly displayed by dizziness of the head, tinnitus aurium, or deafness, or in the rapid subsidence of all the urgent symptoms. In the latter event, three or four grains of the quinine should be administered three times a-day, and the patient supported with good beef-tea, or other light nutriment, and wine, if necessary. Should the urgent symptoms return, the large and repeated doses of quinine must again be resorted to. Slops should be avoided, and purgatives also, unless obviously indicated, but an emetic of tartarised antimony will often prove useful at the commencement, and apparently renders the system more obedient to the specific influence of the remedy.

"Should the urgent symptoms persist, notwith-

standing the administration of five or six doses of quinine, or should dizziness or tinnitus aurium supervene, the medicine must be discontinued,* and after an interval of six or seven hours, small and repeated doses of tartar emetic should be resorted to, until full vomiting is induced; then allow your patient to rest for twenty-four hours, and recommence the quinine as before. When there is much restlessness and want of sleep, a full dose of liquor opii sedativus, with some drops of nitric acid, will often prove highly advantageous, and enable you to resume your treatment with more prospect of success.

"Should the symptoms still resist, you may repeat the remedies successively, as above, for four or five days, and unless the beneficial effects are broadly marked within that period, we can no longer reasonably hope for success from this treatment; and it may be abandoned, or the quinine continued in smaller doses."

This method, to which Dr. Dundas has subsequently given the name of "cinchonism," has according to his statements in his work, and in his essays on the subject published in the *Medical Times* and *London Journal of Medicine*, been tried, with marked success, in the Liverpool Northern and Fever Hospitals, and in other institutions. In the May number of the last-named periodical, however, we find Dr. Dundas complaining that cinchonism has not met with that support which it merits, and that even one physician of note had stated—rather unphilosophically we must say—that "he dared not try it," and that "he did not like fever-curers." Now we think, that such an important question as the effect of Dr. Dundas's treatment of typhus fever, ought not to be summarily disposed of. Let the method be tried impartially, under every variety of circumstance; let evidence for and against it be collected; and let it be judged by the results which it produces. To this, we are sure, Dr. Dundas can have no objection.

The remainder of this lecture is occupied with some remarks on the *exciting cause of fever*. This is believed by Dr. Dundas to consist essentially in exhaustion of the nervous and vascular systems, followed by exposure to great change in temperature. The doctrine of marsh effluvia again comes under animadversion; and some prophylactic rules for visitors to tropical climates are laid down.

Lecture VIII. contains some interesting remarks on the causes of salubrity in Bahia, on certain questions connected with its hygienic

* In the appendix to his work, Dr. Dundas states that "the super-vention of deafness or tinnitus aurium does not always indicate a necessity for suspending the remedy."

condition, and on certain diseases prevalent among the Brazilians.

Lecture IX. contains a sketch of the state of the medical profession in Brazil. There are two natural faculties of medicine, one at Rio de Janeiro, the other at Bahia; both are alike, and modelled very nearly after the constitution of the *Ecole de Médecine* of Paris. Gratuitous services, on the part of medical men, are unknown.

"In cases of accident or sudden emergency, an officer of the hospital not being at hand, another practitioner is immediately summoned, and paid his regular fee. In fact, seeing that the barrister, the attorney, the priest, and every other class of the community, exacts remuneration—and large remuneration too—for time and services, the Brazilian cannot be made to comprehend the grounds on which the *doctor alone*, after long years of study and expense, can be expected to devote his time, his health, and talents, gratuitously to the people. The liberal and enlightened British public will, no doubt, open wide their eyes at such unanswerable evidence of barbarism and defective reasoning powers, in a nation making pretences to civilization; and the proof will, I fear, be deemed too conclusive against my friends on the other side of the line, to admit of my advancing a single word in their defence. I may be permitted, however, to urge in mitigation, that people often view matters differently to the south of the Equator. Be this, however, as it may, one thing is quite certain, that the Brazilian, is a much more independent agent than the British, physician.—pp. 387—8.

We must now bring our notice of Dr. Dundas's work to a close. Many interesting passages we have been reluctantly compelled to pass over; but we hope that this will be fully compensated for by the extensive circulation of the books. It is evidently the production of an original thinker—one who observes *facts*, and reasons from them. An endeavour to bring his views prominently before the profession may give to Dr. Dundas the appearance of being unduly prejudiced in their favour, yet we find him allowing that quinine will not always cure fever. We recommend the book to the careful perusal of every practitioner, who, though he may not feel himself justified in embracing at once all the views propounded by the author, will find in it abundant material for reflection, and valuable hints for practice.

The Stomach and its Difficulties.—By Sir JAMES EYRE, M.D., Edin., Licentiate of the Royal College of Physicians in London, Consulting Physician to St. George's and St. James's Dispensary, &c. London: Churchill, 1852. pp. 152.

ARMED with his trusty weapon of oxide of silver, Sir James Eyre, again proclaims him-

self the champion of the dyspeptic, and the redressor of all the injuries inflicted by that "mischievous and dangerous, because powerful despot," the stomach. And surely we owe a debt of gratitude to the memory of William the Fourth, for having so sagaciously discerned the merits of the modest country practitioner, the Mayor of Hereford, and for having, by conferring on him the honour of knighthood, caused him to shine as one of the benefactors of the human race.

The worthy knight, after a graceful flourish of trumpets in the form of a preface, most lucidly describes the anatomy and functions of the stomach and its attendant satellites. Who among us can fail to receive instruction from such descriptions as the following:—

"The two next portions of the small intestines, (called jejunum and ileum) furnished as has been said, with an inner delicate secreting membrane, and, like the stomach, with another of a muscular texture, pass on the prepared fluid through their long tubulated structure, which is supplied by another description of vessels which permeate the canal; and these, marvellously,—where all is marvellous!—by a selective property, absorb from the stream as it flows, its nutrient and valuable portion. They then convey this to a receptacle by the side of the spine, and finally, this new purified product is distilled drop by drop into a vein, which is passing to the heart and lungs, that it may be perfected by the action of the oxygen of the atmosphere into the blood—the grand vital fluid of the body, from which all the various secretions are formed."—pp. 8—9.

Having described the enemy, Sir James presents us with an equally instructive view of some of the modes of annoyance which he follows, and of the means whereby we may keep the rebel in proper subjection. And we learn that the wealthy among us have erred greatly in departing from the good old mediæval custom of "keeping a jester for after dinner use; he would be well worth his keep and his salary, too, if he were a clever fool." Many an unfortunate wight would then, while aiding the digestion of his employer, by his jokes, be enabled to remedy the great difficulty of his own stomach—that of getting it filled.

But we must pass on to notice the good knight's panegyric on his trusty weapon—

"The oxide of silver is the best and safest, because the most sure, medicine that we have in most, I do not say in all, cases of dyspepsia. Having prescribed it more frequently than any other living physician, once daily, generally much oftener, in various ailments, during the last ten years, (since July, 1841,) and

watched its effect with entire fidelity, aided by many enthusiastic friends, any objection to its use, from any quarter whatever, passes by me as wind and vapour, against the deep conviction of positive indubitable experience. *Time will settle the question and I desire no other arbitrator.* Every observing medical man must have valuable information to communicate, which, neglecting to record, is lost to his brethren for ever; for myself, not writing for self, though loving employment, it is my intention, so long as I may live, to treasure up and publish from time to time, any practical points that I may have the good fortune to discern. Not to overload this work, which has a general, and not a particular object, I purpose recording the written reports of my professional friends upon the oxide of silver in dyspepsia, in an appendix, but shall, *at the risk of being considered an empiric by those who know me not*, allow a few of my grateful patients—and I promise that they shall not be so numerous as to tire—to speak for themselves as to the good which they have derived from the medicine in their respective cases. *

* * * The oxide of silver is tonic and a sedative of the first class, in dyspepsia and diarrhoea.

* * * I have never said or written a word to my medical brethren respecting the pre-eminent qualities of this admirable medicine, that I could not entirely justify; and whether they take it up generally or not, is of no consequence to me individually, so long as I feel that I have presented to them, with the purest intention, a faithful report of a very large experience."—pp. 112—114.

And, now, what sufficient acknowledgements can be given to Sir James, of the inestimable services he has rendered. Payment in gold coin is to him distasteful; an offer of silver coin is repelled with noble disdain. A "respectable tradesman in Piccadilly," once presented him with a testimonial in silver, bearing on it "a grateful inscription to me—his successful physician." But how shall the multitude acknowledge the benefits received from him? Shall not there be a shield of silver presented to the good knight, whereon shall be emblazoned his achievements? Dyspepsia, hepatic disease, constipation, and their companions, might be represented as flying terrified on his approach, while health, cheerfulness, and mental activity re-occupy, with gladdened and grateful countenances, the seats to which they had been long strangers. And the restored dyspeptic may point out to his suffering brother, how he also may regain his lost health!

We have written thus far, perhaps, too much in the tone of Sir James's own jester; but in sober sadness we are obliged to maintain that he has not convinced us, by his own experience, of the value of the oxide of silver. In other hands it has certainly failed, though, like most of the

much-vaunted remedies for such a Protean disease as dyspepsia, it may be useful in *some* cases; but this is certainly not saying much for a remedy which Sir James Eyre regards as almost a perfect panacea.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

MARCH 4TH, 1852.

W. H. PARTRIDGE, ESQ., IN THE CHAIR.

Menstrual Fluid Confined in the Uterus by an Imperforate Hymen.—By Dr. FLETCHER.

A GIRL, aged 17, in the Birmingham General Hospital. She had some inflammation connected with the vagina three or four years ago, not having then menstruated. At seventeen years of age no menstrual discharge appeared, and a tumour showed itself in the lower part of the abdomen. By a catheter being introduced into the bladder, that viscus was found pushed into the right iliac region. When the bladder was emptied, the tumour was found in the median line, and pressing upon the rectum. A dense fluctuation was found by the finger in the rectum, and it was evident that there was a considerable interspace between the finger in the rectum and the catheter in the bladder. The hymen was imperforate, and was strengthened by bands of false membrane, which, being broken down during examination, distinct fluctuation was felt against the hymen. Mr. Baker divided the membrane, and from four to six ounces of thick treacle-like fluid issued at the time, and more afterwards. The operation has been followed by symptoms of peritoneal inflammation, for which she is still under care.

The fluid was of chocolate colour, of tenacious semigelatinous consistence. By the microscope it was found to contain cells, and to be chiefly made up of shrivelled blood-corpuscles.

Caries at the Junction of the Upper and Middle Bones of the Sternum.—By Dr. FLETCHER.

The patient, aged between 60 and 70, had been in the Birmingham General Hospital for disease of his heart. Some separation was then remarked between the first and second bones of the sternum. There was evidently pus between the bones; and the extremities of the bones crepitated when moved against each other. He left the hospital. One night he went to sleep under a brick-kiln, and next morning was found dead.

The heart was found much hypertrophied; the first and second bones of the sternum were carious in the part where they were connected with each other, and were completely separated from each other; they lay in a circumscribed abscess, which did not communicate with the mediastinum. The amount of bone destroyed

was not very great. The cartilage of the second rib on either side was carious; it presented a curious worm-eaten appearance, being burrowed into by little holes, extending into the heart of the tissue. The cartilages contained considerable deposit of calcareous matter, and it seemed not improbable that the carious process had consisted in the absorption of this calcareous matter in places. There was no apparent cause for the disease.

Three Cases of Extensive Disease of the Heart.—By
Dr. FLETCHER.

Case 1.—An old soldier, who had served in India, aged 46, a patient in the Birmingham Hospital. Very intemperate. He was labouring under great dyspnoea; had a quick labouring pulse; there were the physical signs of effusion into the left chest, with much crepitation in the lungs; the thoracic effusion rendered it impossible to ascertain the extent of cardiac dulness; the heart's beat and sounds were natural. Treatment had little influence in checking the disease, and he died in three weeks.

There was considerable effusion in both sides of the chest; the left lung was much collapsed. On cutting through the pericardium it was found to contain bloody serum, of so dark a colour that at first it was supposed that the ventricle had been opened, but it was explained by finding a large amount of old pericardial adhesions, and that the bloody fluid was contained in a sac hollowed in these adhesions. The heart was dilated, with only a proportionate amount of hypertrophy; the valves healthy; the tissue of the heart flabby; the liver was cirrhotic, and only two-thirds its normal size; kidneys congested. Other organs healthy.

Here there was no friction-sound to indicate the pericarditis, and the pleural effusion prevented the pericardial dulness from being made out.

Case 2.—Case 2 was an old Irishman. Dr. Fletcher first saw him three years ago. There was then a tremendous rasping-sound under the sternum, connected with the aorta, with dilatation and hypertrophy of the heart. Dr. Fletcher then told him that he had heart-disease, and that he must take care of himself; he forthwith went home, and got drunk. Since that time the Doctor had often seen him walking up the stiff hill of the Bull Ring as fast as he could himself, and the patient applied to him on several occasions. The last time Dr. Fletcher saw him he was going to a sale; he walked with him, and talked of the markets, &c., but Dr. Fletcher noticed that his breath was very sensitive to any acceleration of pace, or increase of hill. He got worse, and Dr. Fletcher then saw him with Dr. Elkington. There was much spasm of the breath, with orthopnoea. The physical signs were unchanged. He died suddenly as he was sitting in his chair, not having been in bed for a year and a half.

There was considerable effusion into both sides of the chest, and into the pericardium; the heart was greatly hypertrophied, and dilated; the valves of the right side healthy; the tricuspid orifice much dilated, but the valve was very large; mitral valve healthy; but to

insert the finger through the aortic valves, was like putting it into a gravel pit, from the enormous amount of calcareous deposit on the sigmoid valves, the finger passed between two rigid stony masses, formed by the ossification of the valves into two concretions; the ascending aorta was much dilated; the lining membrane of the heart was clear, except a spot of thickening in the left ventricle; there was a very large clear cyst at the surface of the one kidney, the tissue of the kidney being healthy; the opposite kidney was somewhat granular.

It should have been stated that the dyspnoea, which occurred in violent fits, was relieved by his hanging by his arms from a high chimney-piece, and the patient used often to adopt this posture. His urine contains albumen.

Case 3.—This case derives considerable interest from comparison with the last. The patient had been labouring under symptoms of heart-disease for about three months before death, so far as it was known. He had had a great deal of mental anxiety two years before, and this continued to his death. This was the only apparent cause of illness, and his friends explained his illness by that cause. Dr. Fletcher was not aware of his having had rheumatism. The symptoms came on gradually and insidiously, and steadily advanced, with little variation. He had great dyspnoea, palpitation, and great engorgement, with pulsation of the veins in the front of the neck.

The heart was found much enlarged, especially the left side; the left ventricle was enormously dilated, and its wall much hypertrophied, though not in proportion to the amount of the dilatation; the columnæ carneæ were greatly developed; the auricle was dilated, but not to an extent proportionate to the ventricle; the right ventricle was somewhat dilated; there was no important disease of the valves, except some atheroma at the root of the aorta; the aortic valves were large, but it was conjectured had become unequal to their office, thus the dilatation of the heart.

Lithic Acid Calculus.—By Mr. MOORE.

This formation weighs about five drachms and a half; it is composed of lithic acid internally, and of urate of ammonia externally, the external layer being evidently of a very recent date. The crystals of lithic acid are plainly seen glistening, but their form becomes much more apparent when examined with a lens. The internal portion is entirely dissolved in boiling liquor potassæ, and when digested in nitric acid, it becomes a deep purple on the addition of ammonia. The external layer emits ammonia when treated with liquor potassæ.

Scrofulous Disease of the Tarsus.—By Mr. MOORE.

The patient from whom this specimen was obtained was a scrofulous lad, aged 14, who had the foot removed for disease of the tarsal bones. The disease was of some eighteen months' standing, and there were numerous openings about the ankle, leading to carious bone. All the tarsal bones are seen to be diseased, the astragalus and scaphoid so much so that their texture

is nearly all lost. The other small bones are not so diseased, but are of a feathery lightness, and very fragile; they contrast very strongly with some forms of diseased bone where the characteristics are hardness and density.

EPIDEMIOLOGICAL SOCIETY.

COUNCIL REPORT OF THE EPIDEMIOLOGICAL SOCIETY,

Read at the Annual Meeting, April 5, 1852.

DR. BABINGTON IN THE CHAIR.

THE COUNCIL, in presenting their second Report to the members of the Society, have much satisfaction in being enabled to congratulate them on the favourable progress made by the Society during the last twelve months.

Since the last annual meeting the Society has continued steadily to increase the number of its members, twenty-two having been added to the list of contributing members, and twenty-three to that of the corresponding members.

The Council, duly impressed with the importance of extending the inquiries of the Society to Foreign and our own Colonial possessions, as well as to the different countries of Europe, resolved to complete the list of Foreign and Colonial Secretaries as early as circumstances would permit. A Committee was accordingly established for that purpose, and the Council have now the pleasure of announcing the following appointments, viz:—

Belgium.—A. Sayer, M.D., 28, Upper Seymour Street, Portman Square.

East Indies.—James Bird, M.D., 27, Hyde Park Square, and C. Finch, M.D., 58, Porchester Terrace, Bayswater.

France.—Waller Lewis, M.B., F.G.S., 18, Stratford Place, Cavendish Square.

Germany and Russia.—E. H. Sieveking, M.D., 3, Bentinck Street, Manchester Square, and W. E. Swaine, M.D., 6, Upper Seymour Street, Portman Square.

Greece and Italy.—C. R. Walsh, Esq., 42, Half Moon Street, Piccadilly.

Portugal and the Brazils.—J. O. McWilliam, M.D., F.R.S., R.N., 14, Trinity Square, Tower Hill.

Sweden, Norway, Denmark, and Iceland.—R. Gordon Latham, M.D., F.R.S., 27, Upper Southwick Street, Hyde Park.

West Indies.—Gavin Milroy, M.D., 30, Fitzroy Square.

The importance of these appointments is daily becoming more apparent. Letters have been received by the Foreign and Colonial Secretaries from various parts of the Continent, from India, and from the Brazils, expressive, on the part of our professional brethren and others in these countries, of their warm approbation of

the objects of the Society, and of their willingness to co-operate with its members, and already some valuable contributions on subjects connected with epidemic diseases, have been received from Sweden, from India, from the West Indies, and from the Brazils.

The Prussian Minister, and the American Minister, have each addressed a letter to the President of the Society, expressive of great interest in its objects, and offering in the most handsome manner to transmit letters and papers from the Society to the countries they respectively represent, and in other respects to aid the operations of the Society. There is also reason to believe that similar facilities for holding communication with other countries will, ere long, be granted by the other Foreign Embassies, and then the Society will be relieved from the heavy postage charges which must otherwise be defrayed from its funds.

The Council, having deemed it would be conducive to the interests of the Society that the first address to the Society by the President should be more extensively circulated amongst its members and the public, caused one thousand copies of this, as well as of the President's second address, to be printed and distributed accordingly.

The Reports from the Secretaries of the various Committees, indicate that their members are making steady and diligent progress in the investigation of the subjects with which they respectively have been intrusted.

The *Small-Pox and Vaccination Committee* have already issued queries bearing on the subject of their inquiry to not less than 1,800 medical men, of whom 527 have had the kindness to reply more or less minutely to the questions of the Committee, and these replies have been tabulated, analyzed, and arranged.

The Committee have likewise put themselves in communication with the Poor-Law Commissioners, with the Board of Health, and with the Registrar-General. These authorities have, with the greatest kindness and liberality, put every document in their possession at the disposal of the Committee, and a vast fund of important information has thus been obtained.

With the view of rendering the investigation as comprehensive as possible, the Committee have been induced to draw up another and very short form of queries which they intend to address to all the Union Medical Officers, (more than three thousand in number,) throughout the kingdom. These queries the Poor-Law Board have most kindly undertaken to forward free of expense. The same form will also be sent to various other medical men. The Committee, moreover, have already put themselves in communication, or are about to put themselves in communication, with the authorities of the National Vaccine Establishment, of the Small-Pox Hospital, of the Royal Jennerian Institution, of the Army and Navy Medical Boards, and of various public institutions throughout the kingdom.

Besides their inquiries in this country, the Committee have sent through the Hon. the Board of Directors of the East India Company, a certain number of their queries to medical men stationed in various parts of India, in reply to some of which a package of letters,

containing much valuable information, reached the Society from Bombay by the last mail.

They have sought and obtained direct information relative to the laws affecting vaccination and the practice of it, as pursued in Austria, in Prussia, and in Sweden. Within the last few days a series of valuable papers have been received from Sweden, the statistics of which have been reduced to the form required for the Report of the Committee. The Royal Ordinance, and other papers in the Swedish language on the same subject, are also being translated into English, through the kind agency of the Chevalier Tottie, Consul-General for Sweden and Norway.

Different members of the Committee have been engaged in examining various published works, reports, and other documents on small-pox and vaccination.

From the great extent of the inquiry thus undertaken by them—an extent, indeed, which has appeared to get constantly larger, as the Committee have proceeded in their labours—it is impossible for them to say when they will be able to present a formal report. The probability is that that they will avail themselves of the permission already granted by the Council, and present a series of reports on the subject. But whatever determination they may eventually come to on this point, they are sure that they will best consult the wishes of the Council, and act most in conformity with the high character and purpose of the Epidemiological Society, by avoiding immature conclusions, and by steadily pursuing their investigations to the utmost extent to which they are capable of being carried with advantage.

As has been stated on a former occasion, the Committee appointed to inquire into the "Condition of Common Lodging-Houses," &c., obtained a sufficient number of replies to the queries issued by them to enable them to present a report, which is now in the hands of the Council. But the important measures which the Earl of Shaftesbury succeeded in carrying through both houses of Parliament, fortunately rendered the interposition of the Epidemiological Society, in a great degree, unnecessary. The working of Lord Shaftesbury's enactments will, however, continue to receive the attention of the Committee.

The Epizootic Committee, conducted by Professor Symonds, of the Royal Veterinary College, assisted by several distinguished members of the veterinary and medical professions, have held several meetings, but circumstances have hitherto prevented their making much progress in their operations. They nevertheless continue to receive assurance of valuable co-operation from various parts of the country; and the Honourable the Board of Customs have kindly directed their Inspector of cattle to give the Committee such information as he may be enabled to afford regarding the diseases affecting foreign cattle imported into this country.

The Hospitals' Committee.—This Committee, appointed to inquire into the epidemic diseases prevailing in public hospitals, have completed their comprehensive form of queries, which is now being printed, and will be immediately circulated extensively amongst

physicians and surgeons of the various hospitals throughout the kingdom, and others of the profession from whom information on the various subjects embraced by the Committee is likely to be obtained. Among other Committees contemplated by the Council, it is intended to institute Committees to investigate scarlet fever and other epidemics which affect the human race; likewise the potatoe disease, and other diseases affecting the vegetable kingdom. But the formation of these Committees, as well as the successful carrying out of the objects of the Committees already existing, depend greatly upon the assistance which the Society may receive from the profession and the public.

The Council are happy to announce that several handsome pecuniary donations have been lately made to the Society, which will be more particularly noticed in the Report of the Finance Committee. They also gratefully acknowledge that some valuable books have been presented to the Society since the last annual meeting. To the medical press the thanks of the Council are eminently due for the publicity they have uniformly given to the transactions at the Society's meetings; more especially for the warmth with which they urged upon the profession the necessity of their forwarding the objects of the small-pox and vaccination committee.

The Council, then, in looking back upon the events of the Society during the last twelve months, cannot but consider they have reason to be satisfied with its progress, and with the impression it has already made upon the general and professional public.

Judging from the additions that have been made to the numbers of the ordinary and corresponding members; from the papers that have been read at the ordinary meetings, as well as from the discussions that the reading of those papers have excited; from the extent to which the Society is gradually opening up communications with other countries; and from the manner in which its operations have all along been noticed and promoted by the public press, and more recently by some from Government Boards, and the various representatives of foreign powers in London, the Council feel themselves justified in anticipating that the Epidemiological Society is destined, at no distant period, to occupy an important position among scientific societies.

Second issue of Questions on the results of Vaccination.

1. If vaccinated, at what age?
2. " the number of cicatrices?
3. " the special character of ditto?
4. " have you been much exposed to Small-Pox?
5. " have you taken S.P., and when?
6. " and taken S.P., was it mild or severe?
7. If inoculated, at what age?
8. " have you taken S.P., and when?
9. " and taken S.P., was it mild or severe?
10. " have you taken Cow-Pox accidentally or experimentally?
11. If neither vaccinated nor inoculated, have you taken Small-Pox?
12. What is your opinion of the efficacy of vaccination as a protection against Small Pox?

Foreign Department.

On a Stethoscopic Indication of the Separation of the Placenta.

M. Caillant (*Thèse Inaugurale Paris, 1852*) informs us, that while engaged assiduously in the practice of obstetrical auscultation, it occurred to him to investigate the relations between the cessation of the placental bruit, and the disruption of the placenta from the uterine surface. While thus occupied, he accidentally made the discovery of a peculiar and characteristic sound, heard immediately after the expulsion of the child, and which he at once attributed to the peeling off of the placenta. In order to ascertain with certainty that this sound was so produced, he has been in the habit of auscultating the uterus during the whole process of labour, and thus made out that the sound in question was only audible immediately before the placenta was felt in the vagina. This sound consists in a repetition of cracklings, of considerable intensity, beginning and subsiding with each uterine contraction. It is said to be very different from the muscular bruit attending the contractions of the organ, as well as from the placental bruit itself, and more nearly resembles the dry crepitus of emphysema than any other known sound.

Dislocation of the Clavicle Backwards.

Dislocation of the clavicle backwards is comparatively a rare accident, a case or two from time to time being placed on record. One such is published by M. Foucard, (*Revue Médico-Chirurgicale, Feb., 1851*), which occurred in a woman who, while endeavouring to move a cart by pushing against the wheel, got jammed between the wheel and the wall. She was bled next day, but her symptoms becoming severe, she was subsequently minutely examined. It was then found that in the place of the natural projection of the head of the right clavicle, there was a distinct hollow, and it was evident that a luxation backwards had taken place. The author made many attempts to restore the bone to its place, but without avail, and therefore contented himself with subduing the inflammation by leeches. The patient recovered and now is only conscious of the accident when she is called upon to make unusually great exertion.

Cauterization of the Glottis in Whooping Cough.

M. Joubert has published the results of his experience of this mode of treating whooping cough. He has treated in all 98 cases in this manner, but he excludes 30 of these as not being worthy of reliance. The remaining 68 cases he divided into three series, according to the period at which the treatment was commenced. Of these, the general results were, that in 40 the cure was rapidly effected, in 21 a marked relief was experienced, and in seven cases only the treatment failed altogether.

Lupus Cured by Enormous Quantities of Cod-liver Oil.

L'Union Médicale mentions a case of lupus in which the ulcerations cicatrized under the influence, or during the administration, of cod-liver oil. The patient was a young man, aged 23, residing in the country, and was admitted into the hospital of Ghent on the 6th of December, 1850. The disease had manifested itself in various parts of the face and chest, and was of old standing. After purging and rest, half a pound of oil was given in the day, two equal halves being taken morning and evening; the daily dose was gradually carried to three pounds, with occasional interruptions when the appetite failed, or diarrhoea came on. The patient was in the mean time well fed, had wine and beer, and the ulcerated spots were successively touched with tincture of iodine, lemon-juice, and nitrate of silver. In the space of about seven months the cure was complete, all the lupoid ulcerations, to the number of three or four, were completely cicatrized, and the patient had purchased this result by swallowing during that period 265 pounds of cod-liver oil!

[We have long entertained the conviction that lupus is a disease of scrofulous nature, and like other manifestations of that cachexia, is more benefitted by cod-liver oil than by any other medicine. We have thus treated several cases successfully, but never found it requisite to administer more than a table-spoonful thrice in the day.—Ed. P. J.]

On the Habitual Presence of Sugar in the Urine of the Aged.

The *Gazette Médicale* of last month contains an article on this subject, which is suggestive of important reflections on the pathology of diabetes. Our readers will remember the researches of MM. Bernard and Barreswill, which seem to prove that sugar exists normally in the urine, whatever diet be used, and that this saccharine elaboration by that organ is dependent upon the action of the pneumogastric nerve. A further question must, however, be appended to this discovery, viz., what becomes of this sugar after it has gained access to the general circulation? What is its use, and how is it eliminated? Although differing in their opinions on some points of this inquiry, most physiologists agree, that it is eliminated by combustion in the lungs, and one M. Reynoso has further sought to establish (*Provincial Journal, January 7.*) the fact, that when the respiratory process is impeded, sugar is excreted with the urine, and has by experiment ascertained that sugar may thus be made artificially to appear in the urine. Thus far our information on this interesting subject had reached, when a new element was infused into the inquiry by the researches of M. Dechambre.

It occurred to this pathologist, that if M. Reynoso's theory be correct, sugar ought to be found in the urine of aged persons, as in them the respiratory functions are notably diminished in activity; he accordingly undertook some investigations, the result of which has been to induce him to announce, *that sugar is an habitual ingredient in the urine of the aged.*

General Retrospect.

PRACTICAL MEDICINE.

On the Nature and Treatment of Epilepsy.—By Dr. RADCLIFFE.

In a paper read before the Medical Society of London, Dr. Radcliffe drew attention to the *temperament* of epileptics, and showed that this was distinguished by unequivocal marks of weakness and depression; signs of scrofula or some other cachectic disposition, of depressed and feeble circulation, of defective nervous activity, of muscular feebleness, might always be detected, but never the signs of true plethora or of hyper-activity in the nervous or any other system. After describing the phenomena of epilepsy, he proceeded to point out the continuance of the same signs of depression and exhaustion, and to show that the change which had taken place was always one of aggravated depression and exhaustion. This he did by a special examination of the condition of the vascular and nervous systems. Immediately before and after the fit the pulse was shown to be weak and collapsed, and often irregular and slow, and in the fit itself little or no blood was found to be propelled into the vessels. This condition of the circulating system entailed a corresponding failure in the activity of the several nervous centres. Dr. Radcliffe then insisted upon the absence of any local disorder as a cause of epilepsy, and said that the only way in which any such disorder had to do with the matter, was in aggravating the general debility and prostration of the system. Under this head he went on to notice the views of Dr. Marshall Hall. He contended that in epilepsy there was no proof whatever of any increased irritation in the spinal cord, any more than in the medulla oblongata and brain, but that there were abundance of proofs of a directly opposite condition. He doubted that trachelismus and laryngismus, with the consequent cranial and cervical engorgement, had any necessary connection with epilepsy. He did this because there were distinct contractions in the limbs and elsewhere, before the occurrence of the spasmodic tightening of the muscles of the neck and larynx, and because the fit ceases when the congestion was at its height—so that he conceived Dr. Hall's theory had two insuperable difficulties to contend with, the one that the fit had actually begun before it ought, (that is to say, before the congestion had showed itself,) the other that it ceased when it ought to have been most violent, (that is, when the congestion was at its height.) Dr. Radcliffe argued also against the hypothesis of trachelismus and laryngismus, from its non-applicability to very many cases of epilepsy, in which cases, and in many other convulsive disorders, no such phenomena could be detected. He said further that this hypothesis did not account for the insensibility of epilepsy, for, in his opinion, this insensibility (which was much more frequently of the nature of syncope than coma) was, as a general rule, due to a syncopeal condition of the circulation rather than to any venous congestion in the vessels of the brain produced by the spasmodic tightening of the muscles of the neck. The mere violence of

the muscular contractions or convulsions in epilepsy, Dr. Radcliffe said, was no objection to the existence of the most positive prostration and depression; on the contrary, this very phenomenon was the best proof of the existence of that state. Muscular contraction, physiologically as well as pathologically, was always (he asserted) the sign of some withdrawal of the nervous and other stimuli which appertain to the muscles, and never the result of the communication or importation of these stimuli; and for the confirmation of this opinion he referred to his published views on muscular physiology and pathology, and to the facts which had just been stated in connexion with epilepsy. Upon the treatment, he argued at some length against low diet, and in favour of the most nutritious food, with stimulant and corroborative drinks, and against over-exercise in favour of *rest*. Citing many other arguments, he conceived that the non-existence of vascular or nervous excitement, and the existence of a directly opposite condition, was itself an insuperable objection to bleeding and purging in this malady, and an argument for the necessity of stimulants and tonics, and all means which could corroborate the system. Narcotics, counter-irritants, and emetics, were condemned. The convulsion-exciting properties of strychnia were stated to be an argument against rather than in favour of that drug. He objected also to tracheotomy in the cure of epilepsy, on the ground that there are many cases of that malady in which the larynx was not sensibly affected, and in which the impediment to the respiration was rather owing to irregular action or 'spasmodic fixation in the thoracic muscles and diaphragm, than to mere closure of the larynx.'—*Lancet*, May 1, 1852.

On the Curability of Aortic Aneurism.—By Dr. O. B. BELLINGHAM.

Dr. O. B. Bellingham has recently read a paper on this subject before the Surgical Society of Ireland, in which he professes himself more sanguine in his expectations than physicians in general. We give the deductions which he draws from the details of his cases and observations. These are—

- 1st. That aneurism of the aorta is not necessarily an incurable disease.
- 2nd. That it appears to be more amenable to curative treatment than is ordinarily supposed.
- 3rd. That treatment ought always to be especially directed to this object.
- 4th. That when a spontaneous cure occurs, it is always by the gradual deposition of the fibrin of the blood in layers within the aneurismal sac until it is filled up.
- 5th. That if we hope to succeed in effecting a cure, it must be by imitating the mode in which Nature brings this about.
- 6th. That in order to favour the gradual deposition of fibrin, we should aim at diminishing the mass of blood, and lessening the strength and rapidity of the current through the aneurismal sac.
- 7th. That this can only be indirectly accomplished by acting upon the general circulation.
- 8th. That neither bleeding, purgatives, diuretics, digitalis, nor the various other remedies which have

been employed in this disease, can be depended upon for producing these effects.

9th. That an extremely restricted diet, particularly in fluids, continued for a certain time, appears to have the effect of rendering the pulse small, compressible, and slow, and at the same time of diminishing the mass of blood.

10th. That the cases related afford evidence that these results may be brought about by treatment conducted upon the foregoing plan.

11th. That this method of treatment, to prove effectual, must be steadily and perseveringly carried out, and must be continued until a decided impression is made upon the disease.

12th. That it is adapted not only to aneurism of the thoracic and abdominal aorta, but to aneurism in any of the immediate branches of these vessels. And that if employed as a preliminary to compression, pain will be diminished, and the duration of the treatment considerably abridged.—*Dublin Medical Press.*

SURGERY.

Dislocation of the Clavicle Backwards.—By Mr. SIBLEY.

Among our foreign notices in the present number is an instance of this accident, in which reduction was impossible. In the following it was stated to be easily effected, the chief difficulty being in retaining the bone in its place after its reposition:—

Mary C., an Irish girl, aged 10, was admitted into the Middlesex Hospital, March 10, under the care of Mr. de Morgan. It appears that, while playing in the street with some other girls, a carriage driving rapidly by at the time knocked her down; but it is stated by those who saw the accident that the wheels did not pass over her. At the time of admission was much collapsed; face pale; skin cool, with slight rigors; suffering from great dyspnoea; respiration anxious, 44; pulse 100, feeble. The head is drawn down on the chest, and there is extreme pain when it is raised. On exposing the chest there is seen considerable tumefaction over the right coracoid process and about the external half of the right clavicle, with some bruising of the integument. The inner end of the left clavicle may be seen distinctly projecting beneath the skin; but, in place of a similar projection on the right side, there is a depression, into which the finger may be thrust, and the clavicular articulation of the sternum felt; this, however, causing great pain and increased dyspnoea. Behind this notch in the sternum the clavicle may be felt, so that the inner end of the bone lies behind the sternum. There is a difference in measurement from the middle line to the acromion of a quarter of an inch in favour of the left side; there is also considerable bruising over the right side of the lower jaw, a slight cut over the right ear, with a more severe one over the left, and a severe laceration of the left little finger.

On placing the knee against her spine, and gently drawing the two shoulders backwards, the bone is easily restored to its proper place, causing obvious relief to the dyspnoea; but immediately on leaving hold of the shoulders, the bone falls back, and the dyspnoea returns. A splint was then placed across the shoulders, with a

pad between it and the spine, the shoulders being drawn to the splint by a bandage. By this means, the bone was kept firmly in its place; pillows were so arranged along the child's back that the splint should not feel uncomfortable. On the apparatus being fixed, she could lean her head backwards, and stated that her pain was much relieved.

She continued to wear a splint till a fortnight after the accident; the bone then feeling quite firm in its place, she was allowed to lie in bed without a bandage. Ultimately the articulation became as firm as on the other side.—*Medical Times and Gazette*, April 24.

Traumatic Neuralgia.—By Mr. SMITH.

The following is an instance of an affection which is not unfrequently submitted to the notice of the surgeon, and which sometimes proves to be altogether uninfluenced by treatment of every description:—

Jane Turner, aged 22, single, and usually very healthy, but somewhat liable to hysterics, and at all times acutely susceptible of moral and physical impressions, applied as a patient at the Westminster General Dispensary, December 17th, suffering most severely from neuralgia of the thumb. It appears that four months previously she had wounded the right thumb, just on the radial side of the last phalangeal joint, with the shell of a crab; this injury was followed by intense inflammation and swelling of the thumb and hand; suppurative took place. Matter was evacuated by a free incision being made in the thumb. After this the inflammation subsided; but, as cicatrization of the incised part took place, the joint became gradually contracted, very severe pain was felt in the part, and this daily increased, and resisted the remedies which were applied.

Mr. Smith found the thumb so much contracted, that the last phalanx was bent nearly at right angles with the first. The member was much wasted, but the joint itself was swollen, and just at the outer side of it was a cicatrix, about half an inch in extent. There was such intense pain when the part was touched, that the patient could hardly bear to have it examined. She stated that the pain commenced at the cicatrix, and that the sensation was continued up her arm to the elbow; it was constant day and night, and prevented her from sleeping, and nothing gave her relief. Her health appeared good, but there was an expression of anxiety on her face. After a careful examination, Mr. Smith considered that this was a case of traumatic neuralgia, and that there was no disease in the joint itself, although it was much swollen and painful; that in all probability some nervous filaments were implicated in the cicatrix, and thus caused the pain; and that the flexor longus pollicis tendon was contracted. He at first determined to try what local applications would effect, and employed ointments and liniments containing morphia and aconite; but there was no alleviation of the pain. After trying these measures for a fortnight, he advised a cold douche to the part, and a preparation of iron internally. This was also without effect, and eventually he had recourse to an operation, which consisted in dividing the contracted tendon, taking care to carry the incision through the cicatrix. This operation was completely successful.—*Medical Times and Gazette*, April 17, 1852.

Traumatic Tetanus Successfully Treated by Indian Hemp.—By CHARLES HODSON, Esq.

Mr. Hodson relates the case of a child, aged seven years, who was struck with a stone over the eye. About eight days after, when cicatrization had been perfected, symptoms occurred which caused the mother to seek medical advice. At this time the affected eye could not be closed; the pupils were dilated; there was partial trismus, and some paralysis of the right side of the face. Two days after, the report is that he is much worse; right eye fixedly open, and jaws firmly closed; great difficulty in swallowing; a few drops passed between the teeth, the attempt producing spasm of the muscles engaged in deglutition; occasional attacks of rigidity of the whole of the frame; some tendency to opisthotonos. His teeth are small (milk teeth) and do not overlap, consequently fluids can be got into the mouth with tolerably facility. Ordered the following:—Grain doses of the resinous extract of Indian hemp every three hours; an enema of compound decoction of aloes, tincture of assafoetida, and water; a paste composed of extract of belladonna, blister plaster, and antimony, to be rubbed in over the whole of the spinal column. Strong beef-tea and milk arrowroot. From this time up to November 7th he got daily worse; the attendants experience so much difficulty in giving medicine and food, from the spasms consequent upon every attempt to swallow, that they could not be induced to carry out the directions, and they were the less disposed to persevere, from a conviction that the boy must die, and an unwillingness to disturb him from the drowsy state induced by the little medicine they had forced down.

The next report is, that the jaws are firmly closed; right eye open and lower lid everted; conjunctiva inflamed; awakes with a cry of horror and rigidity of the whole frame; well-marked opisthotonos; pulse feeble; much emaciated. From this date, by repeated visits, arrangements were made for giving medicine and food regularly, and he took for several days consecutively from a grain to a grain and a half of the extract of Indian hemp every three or four hours, beef-tea, tea with egg, &c. The food was generally given immediately after a dose, as he was then able to swallow better. From the 10th day of the disease he began to improve, although very gradually—recovering by degrees, first the power of swallowing, then of separating the jaws, and, lastly, of closing the eye. The general spasms became less frequent. By the end of the month he was quite well, and continues so up to the present time.

The patient took in nine days sixty-four grains of the extract, in all 162 grains between the 3rd of November and the 3rd of December. The only unpleasant result occurred about November 22nd; when nearly convalescent, and still taking the extract five or six times a day, it appeared to produce considerable pyrexia and conjunctivitis; these symptoms quickly yielded, however, to a brisk purgative and greatly diminished doses of the hemp.—*Medical Times and Gazette*, May 1.

Correspondence.

MESMERISM IN THE "ZOIST."

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—The April number of the *Zoist* contains some amusing romances, and also some challenges to the common sense members of the medical profession; there is also a long letter from Professor Gregory, in which the celebrated bank-note development is mentioned, and its failure—very consistently with mesmerism, evaded. Now, to this gentleman I wrote some time back a very civil note, enclosing my card in an envelope, and requesting it might be read by some member of his Reichenbach Institute, but no notice has been taken of it, and no current of Odyle has flowed from the north to the south. I regret this, for I think it is high time to test this infirmity of the human brain, "mind" I cannot call it; and I reside in a part of the world where there are several magniloquent mesmerists, but I cannot put faith either in their doctrines or experiments. I have seen the same performed by professed conjurors, who tell you at once they mean to cheat you.

Yours obediently,
E. B.

Medical Intelligence.

MEDICAL BENEVOLENT FUND.

The first public festival of this Institution, now in the eighteenth year of its formation, was held at the London Tavern, on Thursday, the 20th instant, the Right Hon. the Earl of Carlisle in the chair. Upwards of 140 guests sat down to an elegant and well-served dinner, amongst whom we observed:—Sir James Clark; Sir Charles Hastings, Worcester; Dr. Forbes; Dr. Sylvester, of Clapham; Dr. Browne, of Dumfries; Dr. Burrows; Mr. Propert; Mr. Erasmus Wilson; Dr. Radcliffe; Mr. C. R. Hall, of Torquay; Mr. Edwin Saunders; Dr. Conolly, of Hanwell; Dr. Bright; Dr. Cowan, of Reading; Dr. Walter Lewis; Mr. Solly; Mr. Sankey, of Dover; Mr. Bottomley, of Croydon; Mr. Toynbee; Mr. Curling; Dr. R. Bennet; Mr. George Sampson; Mr. Squibb; Mr. South; Mr. Day, of Isleworth; Dr. Bushnan; Mr. Lord, of Hampstead; Dr. Begley; Mr. Newnham, of Farnham; Dr. Daniell, of Newport Pagnell; Mr. John Churchill; Dr. Barclay; Dr. Sibson; Mr. G. N. Palmer; Dr. Seymour, of St. George's Hospital; Mr. Clement, of Shrewsbury; Mr. Lowdell, of Brighton; Dr. Jenks, of Brighton; Mr. Hunt; Mr. Bird; Mr. Norman, of Bath; Mr. Eyles, &c. &c. After the cloth was removed, and grace had been sung, the Noble Chairman gave "The Queen," as the first toast, which was drank with every symptom of loyalty and attachment. This was followed by "Prince Albert and the Royal Family," when the President introduced the toast of the evening, in a truly feeling and energetic speech.

viz., "Prosperity to the Medical Benevolent Fund, and the health of Mr. Newnham." The toast was drunk with enthusiastic applause, and responded to by Mr. Newnham, in a speech which addressed itself to the feelings of his audience, and concluded with a stirring appeal to their benevolent principles; after which followed "The Royal College of Physicians, and Dr. Seymour," "The Royal College of Surgeons and Mr. South," and "The Worshipful Company of Apothecaries." Sir James Clark, Bart., then rose, and in an eloquent address, proposed "The President of the evening, the Right Hon. the Earl of Carlisle." Lord Carlisle acknowledged the toast in the kindest manner. The toast next given was "The President of the Provincial Medical and Surgical Association," with which institution the Benevolent Fund had originated. Sir Charles Hastings responded to the compliment with his accustomed fervor; after which Mr. Newnham gave "The Bishop and Clergy of the Diocese, and the Rev. Harcourt Skrine." Mr. Skrine briefly returned thanks. "The Society for the Relief of the Widows and Orphans of Medical Men in the Metropolis, and Dr. Burrows," was then given, and acknowledged by Dr. Burrows in an appropriate address. "The British Medical Fund," "The Medical Benevolent College," and some other toasts followed; and the company separated about midnight, after an evening which seemed to afford a high gratification to all present. Upwards of 500 guineas were subscribed in the room towards the noble Fund.

QUEEN'S HOSPITAL, BIRMINGHAM.

At the weekly Board of the Queen's Hospital, the Rev. Prebendary Gray in the chair;—present, J. E. Piercy, Esq., Messrs. D. Barnett, G. Taylor, E. T. Cox, J. Griffin, M. Banks, J. Suckling, J. Watson, and T. Boucher—the election of Dr. Heslop as Physician was ordered to be entered on the minutes. The Dean of the Faculty, in submitting the communication from the Council of the Queen's College, called the attention of the Board to the fundamental laws of the Hospital on this head. On the occurrence of a vacancy in the staff of medical officers, the rules provide that candidates be invited, not only by public advertisement in the local, but also in the London journals, to offer themselves, and to forward their testimonials to the Council of the Queen's College, on a certain day. On the receipt of the testimonials, the same are submitted to the Professors, who are pledged on their honour, without fear, favour, or affection, to report on the qualifications of the candidate or candidates; not simply whether such or such candidates are legally qualified, but to select the candidate or candidates "who, in their judgment, is or are best qualified, professionally and otherwise," and to specify the grounds which had guided them in making such a selection. The report is then submitted to the Council for their judgment, and afterwards forwarded to the Hospital Board, who are required to take steps to submit the appointment for confirmation by the Governors of the Hospital assembled at their annual meeting. By this plan it is found that the best interests of the sick and suffering are protected, and the candidate

is not compelled to seek his appointment through a lawyer's office, or owe his election to the creation of votes at the eleventh hour, but stands on his own merits. The appointments of the Queen's Hospital are held for ten years, subject to re-election once; and in accordance with this rule the present medical officers will vacate their appointments, subject to re-election at the next annual meeting.

REPORT.

"The Professors in Medicine and Surgery of Queen's College having been requested by the Council to report on the Testimonials of the Candidates for the vacant office of Physician to the Queen's Hospital, specifying the names of such candidates as are in their judgment eligible and qualified professionally and otherwise to fill the appointment, have to report that eight applications have been received, five of which have been withdrawn. That there are now three candidates, Dr. Growse, a graduate of the University of London, 1850; Dr. Heslop, a graduate of the University of Edinburgh, 1848; and Dr. McGregor, a graduate of the University of Edinburgh, 1833. After mature deliberation, and a careful examination of the testimonials of the respective candidates, the Professors report that in their judgment Dr. Heslop appears highly qualified professionally and otherwise.

"It was ascertained that Dr. Heslop commenced his professional studies with a gentleman in large practice in the Staffordshire mining district, where he resided for a period of five years; that he matriculated at the University of Dublin, where he signally distinguished himself by obtaining three honorary University Premiums; that during a period of four years he held responsible appointments in the Hospitals of Dublin and Edinburgh; that his thesis, written for graduation at Edinburgh, 'On some Morbid Conditions of the Heart occurring in Fever,' is among those highly commended; that he has subsequently discharged the duties of resident Medical Officer at the General Hospital, in this town, for more than three years. On his retirement from that appointment, at a meeting of the Governors, at which R. Spooner, Esq., M.P., presided, it was moved by the Rev. J. Garbett, and seconded by the Earl of Dartmouth, and unanimously resolved, 'that this Board accept with regret Dr. Heslop's resignation; and in so doing, they desire to express their full sense of the ability, diligence, and extreme kindness with which he has discharged the duties during the whole period of his connection with this Hospital, especially of the indefatigable care and attention with which he has cultivated the moral and intellectual improvement of the pupils.'

"Dr. Heslop's practical experience, professional qualifications, industry, high moral character, and anxiety to communicate knowledge, are certified by testimonials from Drs. Stokes, Harrison, King, Aldridge, Flemming, Negligan, Gardner, Geoghegan, Bennett, Paterson, Alison, Wilmot, Churchill, Johns, Thompson, Porter, Sapeleton, Hatchell, and by Messrs. Wharton, Bealy, Wilde, Smyly, Ellis, Collis, Barron, Hatchett, Bynd, and Underhill, copies of which will be placed in the hands of each member of the Council. On these grounds the Professors have great pleasure in recommending the Council to appoint Dr. Heslop to the office of Physician to the Queen's Hospital.

"The Professors cannot conclude their Report without remarking that Dr. Grouse's testimonials are of the highest character, and that the perusal of those forwarded in favour of Dr. McGregor afforded them the highest satisfaction.

"Signed on behalf of the Professors,
"WILLIAM SANDS COX,
"Dean of the Faculty."

After a few remarks from Professors Dr. Birt Davies

and G. B. Knowles, Mr. G. Taylor, Mr. Boucher, Mr. E. Armfield, and other members of the Board, the Report was unanimously adopted.—The Vice-Principal instructed the Dean of the Faculty to forward the Report of Dr. Heslop to the Committee of Council of the Queen's Hospital; the appointment to be submitted to the Board of Governors of that Charity for confirmation at their next annual meeting.

EPIDEMIOLOGICAL SOCIETY.

At the meeting of this Society held on Monday, May 3rd, a paper on "Yellow Fever" was read by Mr. Bascome, who, after tracing the origin of the indefinite term "fever," alluded to the various epithets or terms which had been from time to time added by physicians. Dr. Bascome is of opinion that all fevers are essentially the same, character being assigned to them by locality, habit of body, &c., &c.; also, that fever is nothing more or less than nature's attempt at a curative process—nature's effort to repair a breach, as in symptomatic fever, (as for instance in a broken limb,) or to get rid of something inimical to vitality, as is the case in what is termed idiopathic fever; the noxious something invading primarily the main-spring of vitality, the nervous apparatus, causing suppression of the depuratory or secretory functions, thereby oppressing and vitiating the vascular system, and proving more or less lethal according to the extent of impression made on the nervous system. The more immediate purport, however, of Dr. Bascome's paper, was to show that the malady commonly termed yellow fever, vomito negro, the Bulam fever, or hæmogastric pestilence, was no disease *sui generis*, neither was it a malady (as has been stated) of "modern origin;" further, that persons were not exempt from a second or even a third attack. Numerous authors, irrespective of the Dr.'s personal experience, in various parts of the world, for a quarter of a century, were cited in support of the non-specific nature of yellow fever; and with regard to its not being a disease of modern origin, reference was made to Spanish Epidemiology, from which it would appear, that so far from yellow pestilence having originated at the new settlement in Africa, (Bulama,) a little more than half a century ago, it was known both in Spain and Africa nearly 3000 years back, having ravaged towns and places in both countries, particularly those places situated on the Mediterranean shores; and that history specially notices the lethality of yellow pestilence, not only in ancient Carthage, in Africa, but Carthago Nova, in Spain. It was also shown that yellow fever prevailed with great mortality in the United States of America as far back as 1618.

APPOINTMENTS.

Mr. Hartwell has been elected surgeon to the Exeter Dispensary, his three opponents having retired; Mr. Amory, the retiring surgeon, has also been elected Consulting-Surgeon to the Dispensary.

MILITARY. — 6th Regiment of Foot, Assistant-Surgeon Egerton James Pratt, from the 62nd Foot, to be surgeon, *vice* John Murtagh, M.D., who retires

upon half-pay. 10th Foot, acting Assistant-Surgeon, Duncan Robertson Rennie, to be Assistant-Surgeon, *vice* Inglis, promoted in the 64th Foot. 62nd Foot, Cornelius Clark Rutherford, gent., to be Assistant-Surgeon, *vice* Pratt, promoted in the 6th Foot. Hospital Staff acting Assistant-Surgeon, James Joseph Roosemalecoey, to be Assistant-Surgeon to the Forces, *vice* Jameson, appointed to the 87th Foot.

NAVAL.—Surgeon John P. Burke, M.D. (1845), Assistant-Surgeon William E. Hambly (1847), to the *Buzzard*.

STATISTICS OF CANCER.

The Professor of Surgery (Mr. Paget) in his first lecture upon "Malignant Tumours," at the Royal College of Surgeons, made the startling announcement, that persons operated upon for cancer died, upon an average, thirteen months sooner of their disease than those who were not operated upon. The average was taken from upwards of sixty cases, at the same time omitting all those who died from the immediate effects of the operation.

CUSTOMS MEDICAL INSPECTOR.

The Board of Customs have ordered Dr. McWilliam, their medical officer, to take the title of "Customs Medical Inspector." Dr. McWilliam has to attend the officers of customs, and also the coast guard.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 14th instant:—Henry Septimus Beddome, Hudson's Bay; Richard Clarke, Beccles, Suffolk; James P. Drinkwater, Shrewsbury; Richard Anthony Frederick Gurney, Lilburn, Northamptonshire; Harrison Hanna, Belfast; James Graham Hildige, Dublin; George Prown Lambert, Enfield; Robert Lucas, Bottisham, Cambridgeshire; George Thomas William Mugliston, Westham, Essex; William Ashton Shepherd, H.E.I. Co.'s Service; Thomas Sowerby, Loughborough; Godfrey Bingley Wadsworth, Warwick Street, Regent Stræet.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on the 6th instant:—Andrew Muskett Blomfield, Barton, Norfolk; Thomas Boor Crosby, Gosberton, Lincolnshire; Alfred Edmund Gabriel, Collumpton, Devon; Henry James Hernage, Nottingham; William Alfred Johnson, Warwickshire; Christopher Kirby, Halifax, Yorkshire; William Edward Masfen, Staffordshire; Robert Thomas Ogden, Rochale, Lancashire; William Saville, Wakefield, Yorkshire; George Taunton, Oxford.

Gentlemen admitted members on the 13th instant:—Daniel Bailey Balding, Barkway, Herts; Tertius Ball, Liverpool; Alexander Brown, H.E.I.C.S., Steeple Bumpstead, Essex; Edward Vavasour Hemingway, Leeds; Henry Lankester, Poole, Dorset; John Manley, Hurst Green, Sussex; William Mackay Ogilvie, R.N., Boughton Blean, Kent.

UNIVERSITY OF ST. ANDREWS.

List of Gentlemen who had the Degree of Doctor of Medicine conferred upon them, May 7, 1852:—

Francis Ayrton, M.R.C.S. and L.A.C., Liverpool; William Burns Beatson, M.R.C.S., and L.A.C., Peckham, Surrey, H.E.I.Co.S., Bengal; James Strange Biggs, M.R.C.S., and L.A.C., Devizes, Wilts; Charles Blatherwick, M.R.C.S., Titchfield, Hampshire; James Boyd, Lic. Fac. Phy. and Surg. Glasgow, Beith, Ayrshire; Richard Cross, M.R.C.S. and L.A.C., Scarborough; Robert Butterfield Cumming, M.R.C.S., London; James Drummond, M.R.C.S., Ed., Edinburgh; David Duncan, M.R.C.S., Ed., Glasgow; Edward O'Callaghan Foott, M.R.C.S., Cork, Ireland; Benjamin Godfrey, L.A.C., Romsey, Hampshire; Edmund Grosvenor Goulden, M.R.C.S. and L.A.C., Hazel Grove, Cheshire; John Grabham, F.R.C.S., and L.A.C., Essex; Horace Edward Philogonius Johnson, L.A.C., London; William Locke, M.R.C.S., and L.A.C., Hoddesdon, Herts; Charles Martin, M.R.C.S. Ed., Leicester; Samuel Mault, M.R.C.S., Ed., Nagercoil S. Travancore, E. Indies; James Mc Cann, M.R.C.S. and L.A.C., London; Richard Budd Painter, M.R.C.S. and L.A.C., London; George Newport Pickstock, M.R.C.S., Belize, Honduras, W. Indies; John James Ridge, M.R.C.S. and L.A.C., Gravesend, Kent; Francis Salter, M.R.C.S. and L.A.C., Hayes, Middlesex; Samuel Stacy Skipton, London; Thomas James Vallance, M.R.C.S. and L.A.C., Stratford House, Essex; Watkin Sandom Whylock, M.R.C.S., Southwark; William White Williams, M.R.C.P.L., and M.R.C.S., Gloucester; John Wills, M.R.C.S., Wiltshire.

Mr. Benjamin Thomas Moore passed the requisite examinations, but in consequence of an informality in his certificates, his degree was temporarily deferred.

OBITUARY.

November 25th, of consumption, at sea, James E. Partington, Esq., surgeon of the *Lord Stanley* merchantman.

January 4th, at Paramatta, New South Wales, Bute Stuart, M.D.

April 6th, at Cairo, from the effects of a sunstroke, received four days previously, Charles Evans, Esq., late of Margate, surgeon, in his 39th year.

April 26th, at Liverpool, John Hughes, Esq., surgeon, aged 44.

April 26th, at Maddox Street, Bond Street, John Geo. Porter, jun., Esq., surgeon, late of Peterborough.

May 1st, — Day, Esq., Surgeon, of Harlow, Essex. He was found lying lifeless in his garden.

May 4th, at Acomb, near York, aged 54, Horace Brydges Hodgson, Esq., Surgeon.

May 5th, at his father's house, Brentwood, in the 33rd year of his age, Thomas Shuttleworth Butler, Esq., M.R.C.S., Assistant-Surgeon in the H.E.I.C.S., Bombay.

May 6th, at his residence, Claremont House, Cheltenham, Thomas R. Exham, M.D., aged 32.

May 8th, at Lynn, Frederick Manby, Esq., surgeon, formerly of East Rudham, Norfolk, aged 69.

May 13th, at his residence, the Lodge, Bedford, Nicholas Fitzpatrick, M.D., late of the Royal Artillery.

May 15th, in Hanover Street, London, in the 80th year of his age, Wm. Winstanley, M.D., of West Cliff, Preston, one of her Majesty's justices of the peace for the county of Lancaster.

April 26th, in Maddox Street, Matthew Scott Moore, M.D., formerly Superintending-Surgeon of the Madras establishment.

YORKSHIRE BRANCH MEETING.

The annual meeting of this Branch will be held at the Medical School, Leeds, on Thursday, June 10th, under the Presidency of C. Chadwick, M.D. The chair will be taken at one o'clock precisely. The members and visitors will dine together after the meeting.

WM. MATTERSON, JUN.,

Hon. Secretary and Treasurer.

York, May 21, 1852.

TO CORRESPONDENTS.

Communications have been received from Mr. Moore, Dr. Nelson, Dr. Day, Mr. Bottomley, Observer, Mr. Watson, Mr. Foote, Dr. Oke.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

CLINICAL LECTURES
ON THE
PRACTICE OF PHYSIC,

DELIVERED IN THE
THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D., EDIN.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c.

LECTURE XVI.

ON THE MORBID CONDITIONS OF THE URINARY
ORGANS—CONTINUED AND CONCLUDED.

GENTLEMEN,—At the conclusion of my last lecture, which was devoted, in a great measure, to the explanation of the pathological theory of renal degeneration, I promised that, at the next meeting, I should proceed to illustrate the doctrines then advanced by the symptoms of the actual cases during life, and the morbid appearances after death, which promise I now proceed to fulfil.

You are aware that the treatment, in advanced cases, is generally very discouraging. Those in a less advanced stage, which appear either amongst out or in-patients, are also rather unsatisfactory; because they seldom can be observed for a period long enough to enable us to arrive at decided conclusions. They generally recover, again and again, from the accompanying dropsies; and as patients, in their ignorance, believe that symptom to be the actual disease, they commonly remove themselves from observation and treatment as soon as it disappears. They are also apt to view the pain in the loins as lumbago, and so ease it by means of soothing linaments, &c., until the disease has gained head, and compelled them to seek proper advice at too late a period.

Now, to recapitulate a few points of the former lecture, let me remind you that I considered the essence of the disease to consist, not in the albuminous discharge, but in the replacement of the proper gland cells and tubules of the kidney, by non-nucleated cells of granular matter, or oil or fibrin, this being the result either of a simple perversion of the nutritive processes, or of a preceding capillary congestion or inflammation arising from irritant causes, whether sanguineous or extra-sanguineous. Hence the name of degeneration, as indicating a depressed vitality, and consequent inferior organization. This I stated to be always accompanied by a deficiency of the red particles of the blood—and that I believed this accompaniment to be the cause of the disease when it was one of constitutional origin—but to be only a consequence of the disease, when it proceeded from accidental or local derangements. Under the former head, I classed general debility and *anæmia*; and, under the latter, *hyperæmia*, whether arterial or venous. I further observed that each case had its own peculiarities, which could only be learned by experience; and that I was in a position to show that the disease might go on without dropsies in

one person, without dyspepsia in another, without pain in a third, and without albuminuria in a fourth; but that the most unvarying symptom was the condition of the countenance, which, in its highest degree, produced a puffy, pale, and pasty aspect; whilst in an ordinary way it only gave a heavy Flemish expression, difficult to be described, yet easily recognized when once well observed. I shall now proceed to give outlines of the cases, selecting, in the first place, those that were best marked, and perfectly confirmed; and, afterwards, citing a few more, in which the symptoms during life were comparatively slight and obscure, but in which the degeneration, to a greater or less extent, was revealed after death, according to expectation.

The first in the case book is that of Mrs. Fulford, aged 45, leuco-phlegmatic, but spare, who was admitted June 27th, 1849. She stated that she had been subject to uterine floodings for twelve months past, occurring almost every fortnight; that her face and legs next began to swell, and that, for two months before, they had become permanently enlarged; while thirst had increased, and she had become excessively pale. These latter facts were confirmed upon examination. The nasal bones were likewise observed to be depressed, and she confessed to having been once powerfully salivated for syphilis. Complete dulness also existed over the whole of the left side; a slight cardiac murmur was present, and the breathing was oppressed. Her appetite was good, but she had intense thirst. Her urine was frequently passed, but little came at a time. It was highly albuminous, and there was pain in the kidneys, increased under pressure. Renal degeneration, accompanied with effusions into the chest and cellular tissues, was at once evident; and it was also pretty clear that it had been brought about by the successive deteriorations which the circulating fluid had undergone—firstly, from syphilis; secondly, from severe mercurialization; and, thirdly, from hæmorrhage. From her excessively anæmic appearance she was not cupped at first, but took purgatives, and had a large blister applied to the left side of the chest, which treatment diminished, (after a few days,) the swelled appearance of the face and legs; and then she also had a diuretic, sedative, and tonic mixture of digitalis, lytta, and muriate of iron. As this diuretic, however, did not act, and as the pain of the loins continued, notwithstanding her state of repose, cupping was resorted to on the 1st of July. In three days thereafter, the urine having flowed, there was no oedema of the face whatever, though it looked pale and pasty. The breathing was easy, but, (perhaps in consequence of a Dover's powder exhibited,) her bowels were bound, and she had a drowsiness which approached to stupor. Dover's powders or other opiate preparations were now forbidden, and purgatives were had recourse to, under which, along with leeches to the loins, the respirations improved, and the anasarca greatly diminished. On the 5th, she only complained generally of weakness; pulse 104, small and thready. On the 6th, there was very little oedema, and no pain in the loins, but the thoracic dulness continued the same. On the 9th, all oedema had left, and, on this date, the

specific gravity of the urine was 1017 with the albumen, and 1012 without it. At the time of the stupor, it had been only 1011 with the albumen, and 1005 without it. On each occasion the proportion of albumen had been much the same, though the amount of urea and other salts had varied. On the 10th, the thoracic dullness had somewhat diminished at the upper part of the chest, the urine being free. She was very thirsty and restless, but complained of no pain. The cardiac murmur was a little increased; respirations 26, and easy. She was taking, at this time, the *uva ursi*, with conium and soda. On the 12th she lay tranquilly, but was very drowsy; the respirations were down to 14, pulse 92. The thirst had abated, as well as the dullness of the chest, and the urine appeared healthy—so far as related to the absence of albumen—but its specific gravity was only about 1005. There was no return of oedema, but the tongue was brown and dry. All that day she became more and more insensible, and died on the 13th, in a state of coma. Previously to this event, her perspiration had a rank, urinous odour; but on the coma appearing, that symptom had ceased. On opening the body, some remains of serum were found in the left side of the chest, where the lung was congested, but still crepitated. The heart was large, soft, and filled with fibrinous clots. The liver was also large, but of natural texture, as was the spleen. The kidneys, of usual size, were much congested in the individual veins, which were large and dark. The tubular and secretory portions were almost obliterated. The general structure was very pale, and traversed by the above large dark veins; and, on peeling off the fibrous coat, the surface of the kidney proper was seen to be so much tuberculated as to resemble a small brain. Most of the tubercles were the size of mustard seeds; but many were as large as peas, and some were the size of French beans. These latter had softened, so as to contain a semi-purulent matter, such as is found in large tubercles of the lungs. The morbid conditions of both kidneys were singularly symmetrical.

Now, it will be observed, in this case, that it seemed to have sprung from causes of general debility, viz., the severe syphilis, the mercurial salivation employed for the cure of that disease, and the subsequent uterine hæmorrhages. The physiognomy gave the first impression as to the nature of the malady; and, far gone as it was, the treatment led to one gratifying result, inasmuch as she did not die in the agonies of an orthopnoea, such as must have resulted had the oppressive dropsies not been drained off, but from simple coma, consequent on the non-excretion of urea. The disappearance of albumen from the urine, and the simultaneous disappearance of the urinous elements from the secretion of the skin, are likewise notable facts. That the disease was of blood origin seems pretty clear, from its symmetrical development; and that the depositions were of the nature of tubercle, more than of fat, was inferred from the granular appearances under the microscope, and the sanio-purulent matter contained within the tubercles. The disease was here complicated, as it very frequently is,

with other ailments, as such a serious process could scarcely be expected to go forward in the kidneys without deranging all the other allied organs. The next case is of a similar description.

Sarah Whitehall, of Walsall, a housekeeper, of leucopneumatic appearance, and aged 50, was admitted on New Year's Day, complaining of dropsy. She stated that, about two years before, she had had profuse terminal menstruations, immediately after which her legs began to swell, and went on increasing in spite of treatment. She then felt in a condition of great debility. About three months before admission her face also had become puffy, while her breathing was oppressed, and she felt uncommonly drowsy. She had also dysentery during that time.

On admission there was pain in the loins, increased by pressure, and by the effort of rising to an upright position. The legs and arms were swollen, and, in one place, had broken into a sore. The face was still puffy. The tongue, though clean, was indented by the teeth. She was confused in her ideas. She complained of thirst; and her urine was very albuminous, but not scanty. Along with these symptoms of renal disease there was fulness and tenderness of the abdomen, with slimy stools. The pulse was scarcely perceptible; and she also had asthmatic bronchitis, with some evidences of effusion on the brain.

Now, in this case, as the state of the bowels forbade the employment of purgatives, diuretics alone were exhibited, viz., digitalis, lytta, and nitrous æther, while she took mercury and chalk, with Dover's powder, and was ordered to be cupped over the loins to the extent of four ounces.

By the 4th the stools were reduced from six or eight to three in the twenty-four hours, but were still slimy. Nothing but serum had been drawn off by the cupping, but yet the lumbar pain was reduced, and the pulse had become more appreciable, and 100. The asthma continued, and she was ordered, in addition to the other medicines, the æthereal solution of lobelia night and morning.

On the 8th there was no wheezing whatever, and the abdomen had resumed its natural flatness, being only moved to one or two stools a day, which were not slimy. The chief, or at least most obvious complications, therefore, were now subdued; but not only that, for, at this same date, the legs had much diminished in size, the skin appearing to be wrinkled, and scarcely pitting on pressure. The urine was plentiful, and clear; the tongue was less swollen; the appetite was improved; the thirst had abated, and the pulse was reduced to 80. The same medicines were continued.

On the 11th the swelling of the limbs, &c., had entirely left; the appetite was good, and she felt altogether easier, but complained of superficial tenderness of the limbs, though the sore had healed up under nitrate of silver; the urine was less albuminous; the pain in the loins, however, had returned, and she felt rather languid; pulse 65; cupping was ordered again, the other medicines were stopped, and she took quinine.

On the 15th the lumbar pain had again left, the thirst was not distressing, and there was no *external* evidence of dropsy. She felt comfortable, as she said, and had walked about the ward; but now mark the result, as illustrative of what I have said in former lectures as to the insidiousness of head affections.

On the 16th, that is, the following morning, after a good sleep, she got up and walked about the ward; she next had two cups of coffee, with bread and butter for breakfast, and expressed herself to those around her as feeling very much better. About half an hour after, however, while sitting up in bed, she suddenly fell back, and expired instantly. There was no rattle in the throat, no scream, nor any other premonitory symptom.

On opening the body the pericardium was found much distended, almost transparent, and quite full of serum. The heart itself was healthy in structure, but flabby, and contained little blood. The lungs were healthy in structure also, but congested. The kidneys were also dark, and highly congested, but, upon close inspection, their structure was observed to be infiltrated with a whitish matter, generally diffused, and not conglomerated into any distinct tubercles. The stomach, intestines, spleen, and liver, were tolerably healthy, but, on opening the calvarium, much fluid-blood escaped, and the ventricles were found enormously dilated with clear serum, which had blanched the choroid plexuses, and deposited an albuminous incrustation thereon.

Now, the obvious cause of the sudden death of this poor woman was the intolerable hydropic pressure which weighed upon both the heart and the brain; and the case is an exceedingly instructive one, as showing how many of the more visible symptoms of a disease may disappear, and the patient even feel comfortable, while death impends at every moment, from the impeded action of certain vital organs, which, as in this instance, may be the last to yield to the remedies. As in the former patients, we here found that a numerous train of evils succumbed to the treatment. The external dropsies disappeared, along with the lumbar pain, the asthma, and the dysentery; and the patient almost flattered herself that, under such appearances, she was cured. But there remained the faint action of the heart, the confusion of thought, and the cuticular tenderness, which two last symptoms, when combined together, I have remarked upon in former lectures as valuable indications of cerebral oppression and irritability; and I exemplified them, at that time, by the case of the young girl Bayley, in typhus fever, who could connect no ideas, but who cried for hours together after the slightest ruffling of the skin, either by the fingers or the bedclothes. In this manner, while half unconscious, she would disturb the other occupants of the ward, night and day; and I have shown you the same combinations of stupor and irritability in apoplexy and other such affections. From the appearances after death in the body of Sarah Whitehall, as regarded the brain and the heart, as well as the kidneys, it might be somewhat difficult to declare which was the original source of this complicated malady. Yet, looking to the first

symptom of the profuse hemorrhage, followed by the dropsical effusions, one is inclined to think that the chief or primary source of the constitutional derangement was the altered condition of the blood, which had obviously produced a general degeneration of the kidneys, through capillary congestion; yet not that their condition might have caused death for a considerable time, but for the exudation which had simultaneously taken place into the bag of the heart and the ventricles of the brain. These already adduced are complicated forms of the disorder; but the next case that I shall cite is of a more simple character, and all the results are more clearly traceable to a primary degeneration of the kidneys—traceable to the chronic stagnation of vitiated or impoverished blood, acting upon the capillaries according to those doctrines of our Edinburgh school, enunciated by Dr. Alison.

Elizabeth Healey, a sempstress, and an interesting and intelligent young woman, of Flemish aspect, aged 20, was admitted on the 2nd of July, 1850. She was of leuco-phlegmatic temperament, full, round, pale, and flabby, and had been ill for two years. She first presented herself as an out-patient, but seeing her condition, I at once advised her to enter the hospital which she accordingly did. On admission she stated that menstruation, previously regular, had ceased two years ago, and that, before that period, she had become somewhat pale, but more so since then. The next change she remarked was the swelling of her legs, on one of which an ulcer ultimately formed, which had been treated in hospital by a surgeon of repute, but had never amended. The swellings at length became so oppressive that she sought hospital aid again. On examination, the countenance was first observed to be pale and puffy, especially under the eyes, while the skin round the nails was tense and shining. The cardiac and respiratory sounds of the chest were natural. The legs were very much swollen, and especially the left thigh, where the ulcer still existed, pale, and exuding nothing but serum. Ascites also existed to a great degree, rendering the abdomen protuberant and tense in the extreme. The girth of the right ankle, as well as of the left, was fourteen inches (the girl being naturally well made), while the right thigh measured seventeen inches and the left twenty-three. The latter part likewise felt very solid, and did not pit under pressure like the rest of the surface, but was hard, resisting, and elastic. She stated that she had only occasional pains in the loins, and that there was none then present. She had to rise frequently in the night time, though inclined to be drowsy, while the urine passed was highly albuminous, of specific gravity 1031. Pulse 76 to 80. Renal degeneration was at once inferred from these symptoms; and, as the bowels were in sound condition, and there was no lumbar pain, she forthwith entered upon a course both of purgatives and diuretics.

On the 5th there was no perceptible change; but on the 9th, that is to say, within one week, the tumefaction of the right lower extremity was so much reduced

that the thigh appeared natural, and the leg only pitted slightly. The left leg was also diminished, but was still of great size, and exceedingly hard. The abdomen had become soft and compressible, and the face was less swollen. The urine was as albuminous as before, but was found to contain abundance of urea. She now began to feel lighter, and expressed herself as getting well, saying she felt no annoyance from the purging and diuresis, but rather was conscious of being stronger.

On the 16th the ascites and anasarca were very much reduced, except that some tumefaction had reappeared about the eyes. The tongue also had become very red, and she had pain in the loins. The specific gravity of the urine was 1020 with albumen, and 1017 without it. She was cupped over the loins at this period, and, as the tongue continued to become brighter and the pulse was small, although the œdema continued to decrease, and she complained of no loss of strength, all the medicines were stopped, and she took only Dover's powder at night. After this, however, the tongue continued quite as red as ever, and the œdema began to increase, with heavy headache and pain in the bowels. These symptoms, she said, had come on ever since the purgative powders had been stopped. They were, therefore, resumed on the 23rd, along with the use of *uva ursi*; and on the 26th the swellings had again abated, the face being of natural size, but waxy pale. On the 30th she again relapsed, the tongue being intensely red, and the abdomen tense. The respirations were 24, and laboured; she was drowsy, and the pulse was 120, very small. Under these circumstances she had frequent eructations of acid matter, for which she had draughts of hydrocyanic acid, with soda; but the disease still made head towards a fatal issue. The swellings increased, the left side of the face and body being much more tumefied than the right. There was great heat of skin, and she was excessively drowsy. The respiration became more and more laborious, she had intense thirst, and the tongue was brilliantly red, except where it was covered with aphthous crusts. On the 3rd of August, after a gradual increase of the stupor, she died in complete coma.

Now, on opening the body, the heart and lungs were found quite healthy in their structure, excepting that the former was rather soft and pale. The abdomen and thorax both contained a large amount of serum. The stomach was pale, but congested towards the pylorus. The liver, weighing four pounds ten ounces, was likewise pale, soft, and degenerate. The whole muscular system was also pale; so were the kidneys, which were thoroughly disorganized, scarcely any part of the glandular structure being present, and the morbid mass containing here and there softened tubercles about the size of peas, composed of pus and granular matter.

This, as you will perceive, was a far-gone case, and the history of it is pretty similar to that of the others. There was evidence of tubercular diathesis in the condition of the skin at the roots of the nails; and yet there was no affection of the lungs. But we have, first, some deterioration of the blood, leading to suppression of

the menstrual discharge; in the next place, dropsical tumefactions; and then, when these came to be oppressive, she seeks our advice, and thinks, because they disappear in some measure, that she is getting cured. But the fact is, that when the dropsies have come to this extreme, the kidneys are hopelessly disorganized, and all medical aid is useless, except for palliation of the symptoms; though that is by no means an unimportant matter. In an earlier stage of the malady the results of treatment might be different; but the patients themselves do not value the real importance of their symptoms in an insidious disease of this kind, until they become positively irksome.

The next case is that of William Thomas, a miner, admitted on the 3rd of December. His age was 45, and he was of phlegmatic temperament, pale, and puffy. He stated that for the greater part of his life he had been excluded from the influences of the sun and open air; but he had never been of intemperate habits, and both from his appearance and our subsequent three months' experience of him, he seemed a man on whose word we might rely in such matters. He also said he had never had rheumatism, but that eight years ago he had had an attack of general dropsy, since which period his legs had always been more or less swollen; but, until lately, that was all he had to complain of. On admission, his face was pale and puffy; the abdomen and scrotum were much distended, the legs were very œdematous, and the neck and arms were raised into large irregular lumps, by partial depositions of serum. At the same time, though the left side sounded a little dull under percussion, the heart's actions and sounds were natural. He had no pain, nor ever had any, in the loins. He never rose in the night to pass water, and his pulses were only 60 and his respirations 20. On the other hand, his urine, on being boiled, became almost one solid coagulum of albumen, and he had some cuticular tenderness. He was put under purgatives and diuretics, which acted well, and the dropsical effusions began speedily to disappear. From the absence of all specific symptoms, excepting the dropsy and the albuminuria, it is unnecessary for me to read from the case-book the daily or weekly details of the illness, as regards measurements of different parts and the like. Let me but generally observe, that while the urine presented, as before stated, almost one mass of solid albumen throughout, whenever it was boiled, the dropsy—though occasionally fluctuating more or less—did continue steadily to decrease, while his appetite was good and his feeling of general health made him comfortable and contented. He had full allowance of eggs and other forms of generous and albuminated diet; so that, with these and the medicines, he said on the 21st of January, that he felt "very well indeed," at which time the only apparent symptoms of the disease were the paleness of countenance, the albuminous urine, and some degree of anasarca. On the 25th even this latter ailment was almost gone, and he felt altogether personally comfortable. On the 7th of February he had a severe pulmonary attack, and although he instantly had an emetic, with

blisters to the chest, and expectorants, he got worse. The tide of symptoms now set in dead against him. On the ninth he was drowsy, the urine was very scanty, and the cough and expectoration increased. Shortly afterwards he became too drowsy to expectorate, and then there were universal gurglings over the chest. This drowsiness soon increased to a total insensibility, and he died on the 10th at twelve o'clock at night, in coma. The whole body, though apparently well developed, was now found pallid and flabby in its muscular tissue, and all the areolar textures were anasarcaous. The calvarium was somewhat adherent to the dura mater, serum was effused upon the surface of the brain, and the pia mater was much congested. The sinuses were gorged with dark blood, and all the cavities were full of serum; but the organ of itself seemed healthy. The proper tissues of the lungs were not disorganized; but the left one was excessively congested, and had some pleural adhesions. The heart was small, pale, and soft, and thinner than usual in its right ventricle; but the pericardium contained no great amount of serum. The structures proper of the kidneys, had almost entirely disappeared; both the cortical and tubular portions being reduced to one smooth white mass, resembling the boiled milt of a herring, both in colour and consistence. The bladder contained a little urine, and the stomach and intestines appeared natural.

Now, there are some facts connected with this case, which are of the very greatest importance both in a practical and theoretical point of view, if practice and theory are ever to be separated from one another. For you will observe, that a great many of the usual symptoms were entirely absent. Thus, he never had had any dyspeptic suffering, in regard either to nausea or loss of appetite. His bladder had never been irritable under the unnatural discharges, and consequently he had never risen in the night time for purposes of micturition. Neither his heart nor his lungs had become materially impeded in their functions, and even the kidneys themselves excited no suffering whatever. The paleness, the tumefaction, and the albuminuria, were the only signs that presented themselves, and, when the swellings had disappeared under treatment, the paleness was the only thing visible to the unprofessional eye. The albuminuria, therefore, was the sole tangible evidence by which the degeneration was inferred; although, as already stated, there may be albuminuria, without organic degeneration, and organic degeneration without albuminuria. Wherefore, it becomes necessary in this, as in all other complaints, not merely to look for certain usual symptoms of a disease, as stated in text books, but to balance and connect with each other the whole circumstances of each case, small as well as great, and past as well as present, in order to arrive at a legitimate conclusion thereon. Here, for instance, we had a review of the patient's exclusion, in a great measure, from open air and sunlight for a protracted period; we had his paleness, his former attack of dropsy, and likewise his tumefied condition on presenting himself, all leading to an examination of the urine, even though there was no dyspepsia, no lumbar pain, and no frequent acts of

micturition; and when the albuminous state of the urine was thus observed, the previous history and present general aspect could leave little or no doubt as to the organic degeneration. Under such circumstances, the retained effete matters, being dispersed through the system, must proceed to irritate the more delicate tissues through which they circulate, and hence the sudden dangers that are apt to arise in the course of this disease from the supervention of inflammations in the peritoneum, bowels, heart, lungs, or brain. Thomas had been free from such results for a very long period, but they did at last arise. The brain became affected as well as the lungs, and he died, as usual, from coma. While the other organs had remained so healthy and free, life seemed to have been prolonged by their united efforts to effect a vicarious excretion of the deadly elements of the urine, but so soon as the impediment at the lungs not only checked the action of those organs, but of all other organs of the body, then those elements remained paramount in the system, and speedily brought about the fatal issue by their directly narcotic influence.

The next instance of the disease is one of a more cheering character, in which the results go far beyond the expectations entertained of it upon admission. It is that of Emma Harris, in the second ward, who, as you are aware, has been a long time in the hospital, but whose case was worth every degree of care, time, and attention, that could be bestowed upon it; because, in such a mortal disease, it is of great consequence to prove that arrest, even though it be partial, can be effected; or even if it could not, it is always satisfactory to show that, under such circumstances, life may be protracted and maintained in comparative ease for an indefinite period.

This young woman, aged 28, was admitted in September, 1850, labouring under ascites, anasarca of the lower extremities, swelling of the face, and pain in the loins. She had nausea, headache, and other dyspeptic symptoms, with the Flemish expression of countenance, the shining skin round the roots of the nails, and the pale indented tongue. Her cheeks had some colour, but were paler than they had been. She felt much inclination to drowsiness, but yet had to rise several times in the night to pass water, and menstruation had not occurred for about four months. The urine was excessively albuminous, inasmuch as it became, under heat and nitric acid, almost one solid or custard-like mass, and, upon subsidence, occupied fully one half of the test glass, or fifty per cent. She stated that she had first had the dropsy twelve months before, which had been treated as from cardiac obstruction, but, on consulting Sir Charles Hastings, he had told her friends it was the kidneys that were affected, for which she was in the Worcester Infirmary for a time, until she got relieved of the swellings, which, however, had returned. Under these circumstances, blood was abstracted from the loins, and a belladonna plaster was subsequently applied, while she took purgatives, diuretics, and sedatives. From these appliances the ascites and anasarca were not long in disappearing; she became less drowsy, the lumbar pain lost its acuteness, the headaches were

relieved, and the appetite improved. Still she was pale in lips, tongue, and eyes; her skin was dry, harsh, and papillated; and the pain was not gone. She still rose in the night, and the urine was as albuminous as ever. The belladonna plaster was now constantly worn, and leechings were resorted to only when the pain became at all increased. The principal treatment, in addition, consisted in the employment of tonics, sedatives, and nutrients. Hence she habitually took the muriated iron in conjunction with conium or morphia, in a stomachic bitter infusion, and had ample supplies of albumen, in the form of eggs, &c. It is needless to go minutely over the lengthened registered history of this case, because only one indication was pursued throughout, and I shall now merely point out the chief changes which were observed from time to time, at somewhat distant intervals.

Thus, in April, six months after admission, it is noted that there had been no return of anasarca, or puffiness of countenance; that the bowels were regular and appetite good, and that her colour had improved, while the albumen was in some degree diminished. On the 4th, her cataminal discharge also returned, after a pause of about ten months. In the course of this same month, however, she had some very alarming attacks of peritonitis, and pleuro-pneumonia, giving rise to great febrile excitement, and much fear of a fatal issue. There was great pain, a flushed countenance, and a foul tongue, pulse 128, and respirations 24 and laboured. In this condition she was treated by blisterings, antimony, calomel, and expectorants, and recovered; after which, the general constitution again improved under the exhibition of carbonate of iron, and the calcareous phosphate, with the belladonna plaster and edible nutrients as before. In May and June she rose only once or twice in the night time. In the beginning of July the albumen was much the same as it was in April; but, towards the end of the month, some diminution of it was reported. At this time, she was wont to make water at 12 o'clock at night, and then lay undisturbed till morning. In August there was another catamenial flow, and she felt altogether comfortable. On examination of the urine at this time it was found to have diminished, after subsidence, to one-fourth of the entire urine—or was twenty-five per cent. instead of fifty, as on admission. She still continued comfortable, and again, after further gradual diminution, it was found in October to be only one-eighth part of the urine passed, or twelve and half per cent., and she rose only once in the night time. Her personal appearance, both in figure and countenance, was now so good, that unprofessional or ignorant visitors were wont to wonder what could be the matter. The reduction of albumen, with increased feeling of comfort still went on, and, on the 5th of December, it was reported to be only one-sixteenth part of the urine voided, or six and a quarter per cent. From her long continuance in the hospital, she left on January 30, perfectly comfortable, (so far as her sensations were concerned,) and looking rosy and plump. She had some supplies of the carbonate of iron, and calcareous phosphate out with her, (as she lived a con-

siderable distance from the hospital.) I have seen her since, and she has suffered, as yet, no relapse. Here there seemed every evidence of a primary blood disease, inducing capillary congestion and all its consequences, and, no doubt, there is disorganization of the kidneys, of which, indeed, we may feel almost as certain as if we had seen it. At the same time, there is an obvious arrest of the morbid process, which arrest, (if permitted to be traced to any specific cause at all,) seems fairly due to the occasional abstractions of stagnant blood, the soothing of the local and general irritability, and the persevering supply of those elements to the blood, of which, under such circumstances, it is known to be deficient. Epithelial cells, blood globules, and tube casts, were, from time to time, observed under the glasses, each of which phenomena are readily explainable by the pathological condition of the organ; but how albumen, in particular, escapes in such proportion with the serum, under renal disease, I am not in a position at all to explain, unless it may be due to the fineness of the eliminatory membranes. When it is *clearly* explained, perhaps these diseases may be more under our control, though that is by no means certain; for we often advance in our pathology, while our therapeutics lag behind. Chemistry and the microscope have proved most valuable handmaids to physic; but, after all, we are to bear in mind that, even though this or that disease were found to consist specially in an affection of this or that particular tissue of any organ, yet, unless we discovered, at the same time, that certain special therapeutical agents directly influenced those special parts, we should not be advancing so much as we would desire in the science of curation, and would still have to look, as hitherto, to the great questions of simple increase or diminution, or vitiation, or impoverishment of the blood, or to exaltation or depression of the nervous influences. Think not, from this observation, that I underrate the importance of such investigations, for they add great dignity to our vocation; but I wish to impress upon your minds that you must not despise the old writings of old philosophic physicians, merely because you happen to know somewhat more than they did of the intimate structure of natural bodies; for every advance is only the unravelling of but one more link in the endless chain of causation, or production, the final or primal laws of vital action being always as inscrutable as ever, and totally beyond the grasp of our present faculties. The great generalizations of the soundest ancient philosophers, so far from being exploded by modern researches, are, year by year, gaining fresh illustration of their fundamental truth; and, although they may be sometimes couched in a language not familiar, or even repugnant, to the ear of the present age, no reader, of ordinary penetration, can fail to perceive that they have been the guiding stars of more modern discoverers. Take, as but one example, the speculations of Hippocrates and Galen, but more particularly of Michael Servetus, a Spanish physician, in his *Christianismi Restitutio*, as to the circulation and reactions of the blood. True, we have many such vague, and now obsolete expressions, as

"vital spirits," "animal spirits," "natural spirits," and "subtile spirits." We have also the combinations of "air," "earth," "fire," and "water," mentioned, and their result in "smoke" from the lungs. "*Sanguis inspirato aeri miscetur, et expiratione à fuligine repurgatur,*" &c.; but, turn these expressions into "vital laws," "sensorial and organic life," "carbon," "oxygen," "caloric," "organic and inorganic nutrients," and the favourite modern expression of "*pulmonary combustion,*" and you find that the latter are little more than repetitions of the former doctrines—plus a more minute analysis.

As to the instances that have occurred in the hospital, of paleness and other signs of renal degeneration, without the symptom of albuminuria, or to a very slight degree, I may merely cite:—*Firstly*, the case of Elizabeth Sleuth, who died in the extreme of pulmonary consumption, and whose kidneys were excessively pale and fatty. *Secondly*, of Sarah Binion, who died of carcinoma uteri and dropsy, and whose urine was only slightly albuminous towards the end, but who had the Flemish expression of countenance, in whom the kidneys were very pale, adherent to their fibrous coats, and covered with stelliform clusters of vessels on their surfaces. *Thirdly*, Henry Shaw, who died of cardiac obstruction and hypertrophy, with heavy puffy countenance, but no albumen, in whom the right kidney was puckered on its surface, underneath which puckered part was found a hardened mass, which grated under the knife, the whole being pale, and the middle-third exhibiting no glandular structure whatever. *Fourthly*, in Jeremiah Faulkner, who died of cerebral effusion, and who had an enormous tumour, like an over-grown thymus gland, in the anterior mediastinum, a degenerated hip-joint, and pale puffy countenance, but no albumen, in whom the right kidney, though congested, was pretty natural in general structure, but yet had a tubercle on its surface about the size of a pea, while the left was pale, and so degenerate as to exhibit no proper structure at all, and was rough and unequal on the surface. In all of these, except Sleuth, renal degeneration was diagnosticated during life.

All these facts point to the conclusion which I would wish to enforce, viz., that degeneration of the kidney is similar to degeneration of the lung and other organs; and that, although the exciting causes may often be of a local nature, we are chiefly to look for the evidences of the malady in the general constitutional condition of the patient, and consequently apply our remedies to the part, certainly, but still more certainly, if the expression may be allowed, to the whole material and machinery of nutrition.

As to the other degenerations, simple or malignant, which overtake these organs, and the calculary deposits which take place in them under morbid conditions of the blood, these shall be best treated of when we come to consider the derangements of the blood, and the ganglionic innervation.

LECTURE ON THE DISEASES OF CHILDREN.

DELIVERED IN THE

Chatham Street School of Medicine, Manchester,

By DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Peth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Peth; Fellow of the Imperial Society of Medicine at Vienna, etc.

LECTURE X.—(Concluded.)

Iodine; Mercury; Anthelmintics. External Remedies.

ATONIC diarrhoea, or that which we observe to come on after the disappearance of eczema of the scalp and face, is frequently benefitted by iodine.

There exists an infinite and unaccountable variety in the tolerance of this remedy in different children. I had many cases in which, at the age of two or three years, they took for a long time two scruples of iodide of potassium every day; more than that, however, will seldom be resisted at this age.

The best preparation is the *iodide of potassium*, pure iodine sometimes may be combined with it, for the sake of saving expense, or to act more strongly in some full and phlegmatic constitutions. In general, however, iodine is too irritating for children. The best mode of administering iodide of potassium will be in solution, prescribing two or three drachms to six ounces of distilled water, of which we commence by one or two teaspoonfuls three times a day, mixing each dose with water and sugar. The more water, the easier we convey large doses of the remedy, without causing great irritation of the eyes and the frontal sinuses.

I recommend you to administer two, three, or four doses, but all in the afternoon, thus the reaction will reach its height during the night, consequently in bed, by which circumstance the perspiration is promoted, and the child will be in the morning, and during the greater part of the day, in an easier state. Using this remedy duly in this powerful way, you will succeed in curing cases which have been already treated with it, by small doses, for a long time, and unsuccessfully.

In general you will observe, that all those children whose appetite soon increases after some doses of iodide of potassium, will bear a very effective course of it, whilst those whose appetite soon becomes lessened, in a short time will not bear even small doses.

There are three other salts of iodine, which I will only shortly mention:—

Bi-iodide of mercury, approaching in its action pure iodine, but insoluble, besides that in every respect it is not a remedy proper for children.

Iodide of mercury, approaching in its effects calomel, but less purging, less strong in its antisymphilitic effects, and less salivating, there is scarcely a reason to use it in children's practice.

Iodide of iron.—Iodine acts in a stimulant way upon the secretory functions, whilst iron obstructs. Iodide of iron I have observed to act simply as a martial remedy.

As to *anthelmintics*, children of tender age do not suffer from the *tape-worm*, which in all my practice I scarcely have encountered before the eighth year, even this being a rare case. I have not to speak, therefore, of the male fern, or of the pomegranate root, but to mention only those remedies which have appeared to me the best against the *ascaris vermicularis*, and *ascaris lumbricoides*.

The *ascaris vermicularis* (maw-worm) dwells in the rectum and the lower part of the large intestines, crowded in great numbers, most frequently proper to infancy and tender childhood. The remedies employed to remove them are almost in all countries the same; I will mention to you, however, injections of an infusion of red onion, mixed with some drops, or half a grain, of extract of aloes.

Ascaris lumbricoides is the worm that causes frequent and sometimes severe disturbances from the second year of age, its abode being the small intestine, and sometimes the stomach. I can recommend to you the following powder, which I have found most efficient in the complaint in question:—

R. Pulv. Sem. Santonici,

„ „ Tanacet. utr., dr. ss. —

„ Rhei, gr. xij.

„ Jalapæ, gr. viij.

Sacch. Alb., scr. iv.

F. pulv., to be divided into six or twelve powders, according to the age of the child. From two to three powders every day.

If we are not mistaken in the diagnosis, after a course of four or five days with these powders the worms will come out; if we have been mistaken, which easily happens with this complaint, the above powders, united with a strong reduction of farinaceous food, at least will have exerted good effects upon that condition of the abdomen which resembled helminthiasis.

Mercury is less efficient as an anthelmintic than the above remedy, and should never be given repeatedly, unless there is clear and special reason for its use. If the constitution of the child, however, is strong, and you wish to increase the force of the medicine by the addition of calomel, then I advise you to do this only after you have given, during three or four days, the former powders, and to accomplish then the trial or cure by adding to the three or four last doses two or three grains of calomel to each.

External remedies.—The particular indications, mode of application, and effects of fomentations and poultices, offer no salient points in children's practice. Baths, injections, and sponging are too generally known to require any comment.

Though hydropathy, as a general system of therapeutics, is but an extravagance of the human mind, there is no doubt that some of its means and modes of treatment, in some cases, are good, and worthy of your confidence.

Above all I must bring under your notice the *local cold wrapping*, after the method of Priessnitz, at Gräfenberg; it consists in dipping a proportional piece of linen into cold water, which, after being squeezed out, you put over or around the affected part, then you cover this carefully with another (much larger) dry cloth, so as to prevent the accession of air, as well as evaporation. After a couple of hours, or more, when you suppose or find that all has become dry and hot again, and that the application appears beneficial by its effects, you repeat the same as many times as necessary, even during weeks and months.

The effect of this application is, to subtract at first the superabundant caloric, and subsequently, when the linen has become warm, to serve as a local bath, and promote local perspiration on the affected part. The principal indication therefore is, intense dry heat of the affected part. Abscesses do not allow its use. In articular rheumatism and chronic inflammation of the joints I have found it highly beneficial in children's practice.

With regard to *cold sponging of the body*, I forgot before to mention to you that my experience is decidedly in favour of it, whenever, during the course of a fever, a long-persisting, tense, dry, hot skin, with great restlessness, is before you. Scarlatina, noted by these symptoms, far from excluding its use, finds in general in cold sponging, an incomparable assistance. It soothes the system and promotes perspiration. In typhus, I frequently mix the cold water to be used, with one fourth part of diluted muriatic acid. Counterindications are the inflammations of the organs of the chest.

Blisters and sinapisms are decidedly mischievous with young infants from about one to six weeks old, in particular with a very delicate skin. Febrile excitement will ensue or increase by their use.

If the case shows no symptoms of fever, and that the one or the other of those applications are indicated, the essential condition will be to weaken them, mixing the first with a quantity of diachylon, the second with linseed powder, proportionally to the age. For a child about three months old I never add less than five parts of diachylon to one part of cantharides blister. The same proportion is to be maintained in diluting the mustard poultices with linseed. I have seen ensue dangerous irritations of the bladder after strong and large blisters.

In these lectures I have not mentioned all remedies of which I have ever made use, but all those indeed, which I regard as important, as necessary or useful, and safe in children's practice.

[We are requested to make the following corrigenda in the first part of this lecture inserted in our last number:—Page 257, col. 1, twenty-one lines from the bottom, for "eight ounces of water," read "three ounces;" col. 2, second line from the top, for "chlorosis anemia," read "chlorotic anemia;" page 258, col. 2, sixteen lines from the bottom, for "as we perform them in Bath" read "as I have performed them in Bath."

NOTES ON THE TREATMENT OF CURABLE DISEASES.*

By W. S. OKE, M.D.,

*Extra-Licentiate of the Royal College of Physicians, Physician to the
Royal South Hanpts Infirmary, &c.*

THIS paper, excepting the cause of obstruction from inflammation, was read before the Southampton Medical Society, April 6th, 1852.

OBSTRUCTION OF THE INTESTINAL TUBE.

Intestinal obstruction, whether considered as to the frequency of its occurrence, the severity of its symptoms, the peril in which it at once involves life itself, or the anxiety felt for its result, is perhaps one of the most interesting subjects in pathology.

It may be caused—

- 1st. By inflammation.
- 2ndly. By spasmodic action.
- 3rdly. By over-distension.
- 4thly. By incarceration.
- 5thly. By impassable bodies.
- 6thly. By organic disease.†

I.—Inflammation.

Obstruction of the intestinal canal may be caused by inflammation, when either its peritoneal or muscular coat is involved, as in both cases the vermicular action must often be arrested—first, probably by the congested condition of the part involved; and, secondly, by the deposition of fibrinous lymph. An inflamed state of the mucous coat is not so apt to involve the muscular and arrest the peristaltic action, but, on the contrary, to increase it, and produce mucous diarrhœa.

The exciting causes of idiopathic enteritis are damp and cold, intemperance, constipation, acrid secretions, &c; and the predisposition to this disease is greatly increased by functional disorder of the liver, either exposing the alimentary canal to the effect of acrid secretions, or interrupting the hepatic circulation, so as to produce a congested state of the portal veins, and consequently of the intestinal capillaries. The part of the canal most liable to inflammation is the termination of the ileum, which is situated in the right iliac region. The following is a sketch of the symptoms:—Severe griping pain, which is constant, although it may vary in degree, and the pain may be acute also if the peritoneal coat be much involved. More or less tension of the abdomen, which is intolerant of the slightest pressure. Constipation and vomiting. Sometimes also there will be a local thickening of the parietes over the seat of the disease, from the deposit of plastic lymph upon the peritoneum. The pyrexia will be of the middle kind, tending to asthenia; the tongue furred,

and often somewhat brown along its centre; and the pulse will be small, hard, and 120 in the minute.

Should the disease be inadequately treated in its incipient stage, the obstruction will soon become more complete, with an aggravation of all the symptoms, which in so delicate a structure as that of the intestinal canal, is soon followed by the loss of its vitality, indicated by cessation of pain, subsidence of the abdominal tension, a sunken aspect, imperceptible pulse, and a coldness of the extremities. On the other hand, the disease will often yield to early and judicious treatment. Blood should be at once taken from the arm, to the amount of twelve or fourteen ounces. We are not to be dissuaded from the use of the lancet by the smallness of the pulse; and if it should rise after bleeding, and the pain remain undiminished, the venesection ought to be repeated. At the same time, looking at the asthenic tendency of the febrile action, caution will be required not to take away so large a quantity of blood as shall cripple the reparative power of the system; and if a second bleeding be deemed inadmissible, the seat of pain is to be covered with leeches, and their bites encouraged to bleed by hot stupes of scalded bran in flannel bags, which may be kept afterwards applied as a fomentation. In this stage medicine also will be found of the greatest use in removing the cause of obstruction. Five grains of calomel and one of powdered opium, in the form of a pill, are to be given at once, and at intervals of two hours a pill containing two grains of calomel and half a grain of opium is to be repeated till the pain and vomiting have subsided. Then, and not till then, we may venture to give two or three doses of either of the following mild aperients (1 and 2) every four hours till the bowels are acted upon:—

1.—R. Olei Ricini Opt.

Aquæ Cinnam;
Aquæ Pluvialis, sing, dr. iij.
Tincturæ Digitalis, m. xv.
Misturæ Acaciæ q.s. ad benè miscendum.

Fiat haustus quartis horis sumendus donec operaverit.

2.—R. Magnesiæ Sulph., dr. iij.

Tincturæ Digitalis, m. xv.
Syrupi Zingiberis, dr. j.
Aquæ Menthe Pip., dr. ix.

Misce. Fiat haustus eodem modo sumendus.

The digitalis is added as a relaxant; and I have known it to conduce greatly to the effect of an aperient. But should these medicines be rejected after two or three doses they must be discontinued, and the calomel pill (3) steadily persisted in till the bowels are relieved. If ptialism be produced, success will be almost certain.

3.—R. Hydrarg. Chloridi., gr. ij.

Pulv. Opii., gr. 1-6th.

Misce. Fiat Pilula secundâ quâque horâ sumenda.

Case.—A gentleman's son, five years of age, was seized with severe enteritis, accompanied with constipation and vomiting. Bleeding with leeches, aperients, injections, and the warm bath, having been adopted without effecting any movement from the bowels,

* Continued from page 139.

† Organic obstruction cannot, of course, be considered a curable disease. It has been added to render the subject more complete.

Calomel was persisted in at short intervals, with a view to set up a mercurialism in the system. In about twenty-four hours ptialism happily took place, when the obstruction yielded, and the boy rapidly recovered.

II.—*Spasmodic Action.*

In this case it would appear that there must be an excess of one of the forces of the vermicular action, for if the circular and longitudinal fibres were equally involved, the result would be, increased propulsion and not obstruction; but, on the other hand, when the nice balance between these forces is disturbed, and one of them is in excess, then the vermicular action must be arrested, and obstruction be the result.

Amongst the causes of this kind of obstruction are, saturnine poison, crude indigestible food, such as shell fish, uncooked food, acrid secretions, &c.

The severity of the spasm will depend, in great measure, upon the degree of disproportion which exists between the two forces of the vermicular action, and the saturnine poison appears to be capable of producing this disproportion in the greatest degree.

The symptoms are, vehement paroxysms of twisting pain about the umbilicus, obstinate constipation, vomiting of a green bilious fluid, and retraction of the abdomen towards the spine. The patient is often found in a bent position, pressing the seat of pain with his hands, to mitigate its severity. The tongue is not much furred, the temperature of the skin normal, and the pulse is generally under 100 in the minute.

Painters are frequently suffering from this kind of obstruction, from their being constantly employed in the use of the carbonate of lead; hence it has been called "*colica pictorum*."

This disease, so long as it does not exceed the limit of spasmodic action, generally terminates favourably; but if it should have assumed the character of inflammation, then the prognosis will be governed by such an aggravation.

The indications of cure are:—1st, to relax spasm; 2nd, to restore the normal peristaltic action. The first will best be fulfilled by a full bleeding, opium, and the warm bath. The second by purgatives. Fourteen or sixteen ounces of blood should be immediately taken from the system, followed by a pill, containing two grains of opium, and, if the continuance of the spasm render it necessary, one grain is to be repeated every three or four hours. This treatment will usually succeed in subduing the pain and vomiting, and sometimes act as an aperient also; but if it should fail of the latter effect, the pill (1) is to be taken every hour till the bowels are acted upon:—

1.—*R. Hydrargyri Chloridi, gr. j.*
Extr. Coloc. Comp., gr. iv.
Olei Caryoph. q. s.

Misce fiat pilula omni horâ sumenda donec operaverit.

The warm bath may be used at this period—the temperature 100°, and the patient be immersed twenty minutes, taking care that the temperature be not diminished.

Sometimes the symptoms of saturnine colic are met

with in persons not employed in the use of lead. In such a case the gums are to be inspected, and if there be a blue line along their margin, we may be sure that the patient has been in some way or another exposed to the deleterious influence of this poison; and should he have no recollection of being so exposed, then the water he is in the habit of drinking and using for culinary purposes, is to be examined by proper chemical tests; for, however bright and tasteless it may be, if it contain a free acid, and be kept in leaden troughs, or conducted through leaden pipes, it will decompose the lead, hold it in solution, and become a saturnine poison. It is the free carbonic acid—which, in fact, makes the water wholesome, sparkling, and refreshing—that acts upon the lead; and this quality of water is found not only in various districts of Great Britain, but of every other country; and if persons residing in such districts, not having made themselves acquainted with this fact, reserve such water in leaden tanks, or conduct it through leaden pipes, they have to blame only themselves for having converted a wholesome and delightful beverage into one that is deleterious. I have myself seen, in several districts of Hampshire, the deleterious effects of lead held in solution in super-carburetted water, which appeared to be, and of itself was, of the finest quality. A gentleman, resident in one of those districts, was displeased with my opinion, that the water in his well was impregnated with lead, (although it was manifest one of his family had been long suffering from it,) because, forsooth, many in his neighbourhood were in the habit of resorting to his far-famed spring, from, as he supposed, its superior purity. A farmer, who lived in the middle of the New Forest, consulted me a few years ago for severe colic and constipation, and as several of his relatives from time to time had been attacked with the same disease, and eventually had fallen victims to it, it was supposed to be hereditary. Suspecting that they had been exposed to the deleterious effects of lead, I tested the pump-water used by his family, and found it holding a large quantity of the carbonate of lead in solution. This at once indicated the cause of the disease, and the means of preventing its recurrence.

Some practitioners have called in question the ordinary tests of lead-water, asserting that neither bichromate of potass nor sulphuretted hydrogen, can be relied upon; but when a patient is suffering from the symptoms of colic, when the margin of his gums show the blue line, and when the water he has been accustomed to drink is shown, by either of the above tests, to contain the solution of lead, there cannot surely be any reasonable doubt as to the cause of the disease, or the efficacy of the test.

The blue line along the margin of the gums was first noticed by Dr. Burton, and a most valuable discovery it is, not only on account of the accuracy of its diagnosis, but because it appears to give early information of the carbonate of lead being absorbed into the system. I could adduce numerous instances in my own practice, to show its diagnostic value, but two brief examples will suffice:—

In the summer of last year I was requested to visit a small tradesman, residing in the country, who was suffering severely from intestinal obstruction. As the attack could not be accounted for by any ordinary exciting cause, the gums were inspected, and a well-marked blue line was observed along their margin. As he had not been in any way meddling with paint, the water he was in the habit of drinking was examined by the bichromate of potass-test, and it was found to be largely impregnated with the carbonate of lead. Under a modified degree of the above treatment he recovered, and by avoiding the saturnine causes, the disease will probably never return.

The following case is one of the secondary effects of lead, and I shall mention it in this place, as it showed the blue line in a very remarkable manner:—I was requested to visit a publican and his wife, residing near Otterborne, in Hampshire. The woman had been long confined to her bed, from paralysis of the lower limbs. The husband could manage to walk about the house, as his loss of power was chiefly in the upper extremities. On inspecting his gums there was not only a distinct blue line along their margin, but also a corresponding blue line, as deep as indigo, upon that part of the membrane of the cheek which came in contact with the line upon the gums.

It is almost needless to add, that the water, which they had been accustomed to drink, and which was conveyed through a leaden pipe from a well at some little distance, was found to be saturated with the saturnine salt.

When, from other exciting causes, there is produced a less amount of disproportion in the vermicular forces, although enough to obstruct the bowel, there is a manifest difference in many of the symptoms. Instead of a retraction, there may be a fullness of the abdomen. The pain is more of a persistent, aching character, than returning in vehement paroxysms; and there is less vomiting, indeed sometimes there is none at all.

The curative indication in this case is much the same as in the last,—viz., to subdue the action in excess, and to restore the normal vermicular function of the intestine. If purgatives have failed, they ought not to be persisted in, as they will rather increase the spasmodic action than remove the obstruction. Blood should be taken from the system, and by leeches from the epithelium of the rectum. Opium and calomel are to be given in such doses, and at such intervals, as the degree of pain may require; and this kind of colic will generally be governed by more moderate doses of opium than those prescribed for the "*colica pictonum*." It will be sufficient to commence with one grain of opium, and three of calomel, and this dose may be repeated in an hour, if it should have given no relief, after which it may suffice to give two grains of calomel, and half a grain of opium, every two or three hours, till the pain has ceased. In this case, also, these means will sometimes act as a purgative, as the following case will show:—

A man, of middle age, and married, who had lived in the capacity of a groom in Hertfordshire, came to

Southampton, and took a beershop in one of its close streets. He soon became ill from a disorder of the hepatic function, which resulted in intestinal obstruction. The medical gentleman in attendance had given him purgatives of different kinds, with calomel and opium, but without any effect upon the bowels. As he had been constipated for some days, I was requested to see the case in consultation. There was severe pain of the abdomen below the umbilicus, which was somewhat full, and dull under percussion; there was not much vomiting; his tongue was furred; his urine high-coloured; his pulse not much above the normal number; and his aspect good. I advised that fourteen ounces of blood should be taken from the arm, and that one grain of calomel, and half a grain of opium, should be steadily persisted in every two hours, without any purgative; the following morning I found that he had passed a quiet night, but had had no stool. The blood was not buffed. The pills were ordered to be persisted in every three hours. Early the next day he had a copious discharge from his bowels, of a bilious character, and he was speedily convalescent.

If, however, the bowels should remain inactive, they may be gently solicited; and it will be far better to do this by emollient glysters than by purgative medicines, as by the latter there will be the risk of bringing back the vomiting, and aggravating the spasmodic pain.

Case.—A gentleman, from having been studiously occupied in a warm close room, became bilious, costive, and low-spirited. These symptoms resulted in pain and obstruction of the bowels; the pain was of a severe aching character, situated below the navel, and this part of the abdomen was full, but not tender under pressure. There was no vomiting nor febrile disturbance to any amount. The tongue was furred, and the urine high coloured; various purgatives were taken at intervals, without the slightest effect, and he was bled from the arm to fourteen ounces, and afterwards every effort was made, both internally and externally, to bring him under the salivary action of mercury, but in vain. Drastic purgatives were next tried, and were kept down, but instead of acting upon the bowels they greatly aggravated the pain. Leeches also were applied to the epithelium of the rectum. As all these remedies afforded him no relief, and as he had been constipated several days, he resolved, as a last resource, to give himself, every three hours, a glyster of the muriate of soda, olive oil, and gruel, with Reid's syringe. This treatment he continued till his strength was almost exhausted, when he had the satisfaction to feel the obstruction give way. The faecal discharge was partly clay-coloured, and partly black, accompanied with a quantity of venous blood, the result probably of a congested condition of the mucous coat of the intestine. Evacuations of a dark colour, mixed with blood, were frequently passed for several days, when the secretions improved, and he slowly recovered.

Disorders of the hepatic function, as in the two last cases, are often the predisposing cause of this kind of intestinal obstruction also; and when overcome, the faecal discharges are sometimes observed to be of the

colour of *ta*; but this appearance does not represent what has been termed *melæna*. The difference is this, that in the former the base of the colour is bile, in the latter blood.

During the period of convalescence it is of great importance to make choice of mild unirritating aperients, avoiding all drastic purgatives. The best will probably be Nos. 1, 2, 3, or 4.

But when the obstruction has been caused by the poison of lead, the dilute sulphuric acid is to be combined with the aperient, as recommended by Liebig, with the view of converting the soluble salt of lead, that is acting as a poison in the system, into the sulphate, which is insoluble, and therefore harmless. I have found No. 5 very beneficial in patients suffering from the secondary effects of saturnine poison.

III.—Overdistension.

Obstruction from overdistension may be caused by large evolutions of gas or by fecal accumulation; but although the former may occasionally obstruct the bowel, *per se*, by inflating it beyond the power of contraction, such inflations are more commonly the effect rather than the cause of the obstruction, as will be hereafter shown under another head; the latter, therefore, will be principally considered in this place.

Obstruction, occasioned by fecal accumulation generally occurs in some part of the large bowel, and it is probably produced in this manner. The patient, from sedentary habits and a torpid state of the hepatic function, becomes costive, and every day or every other day has a dry insufficient stool. This goes on for some time; but as he is free from pain, does not feel ill, and has his usual appetite, he takes no particular notice of this state of his bowels, and does not deem it necessary to have recourse to any aperient, till at length,

from the gradual accumulation of the feces in the colon, he can pass no stool at all, and is seized with pain, vomiting, and all the symptoms of intestinal obstruction.

The diagnosis in this case will become sufficiently plain from its history; and by tracing carefully the course of the large bowel from the rectum to the cœcum caput coli, we shall rarely fail to detect at what part of the canal the accumulation has taken place, where there will be fullness, tenderness, and dulness under percussion; but sometimes, doubtless, the diagnosis may be in some measure obscured by the inflation of the bowel.

The treatment of intestinal obstruction from this cause has to be conducted upon principles directly opposite to those indicated in the former. There the indication was to relax spasmodic action. Here it is to excite the action of the bowel.

When we have, by a careful examination of the symptoms, put ourselves in possession of the true nature of the case, it will be at first far better to endeavour to act upon the bowel through the rectum than the œsophagus. A good-sized, smooth, elastic tube, and well oiled, is to be gently carried up into the sigmoid flexure, as recommended by O'Beirn, and through it a copious enema of yellow soap and water, is to be pumped into the colon, when the tube is to be withdrawn. It is necessary to use a full-sized tube, with a smooth bulbous end, which I would advise every general practitioner to keep ready for such a purpose. It will pass up the winding curve of the canal much more readily than a small one, and be less likely to perforate or damage the bowel.

I have seen many instances of the success of this practice, of which I will briefly relate one. A few years ago I was requested to visit the proprietor of a yacht, in Cowes' Roads, who was suffering from obstructed bowels. He was of middle age, and had been living incautiously. Mr. Davids, the medical gentleman in attendance, had adopted many judicious remedies for his patient but without the desired effect. There was aching pain of the bowels and vomiting, and no stool had passed for two or three days. The abdomen was full, dull by percussion, and tender under deep pressure; but there was not much disturbance of the system. In consultation it was decided to throw up a copious enema into the sigmoid flexure by means of a long tube. Fortunately he possessed a capital one, which passed up admirably and conducted the glyster into the gut. The remedy was crowned with success, and the patient recovered. Sometimes our proceedings are stopped *in limine* by the rectum being stuffed with hard masses of fecal matter. If so, they must be removed by some convenient instrument, till room be made for the tube to pass. A few hours after the colon has been injected in the manner above recommended, a purgative is to be given, and its kind must be governed by circumstances. If there is reason to think that the obstruction has been washed away, it will be sufficient to give four grains of the watery extract of aloes and three of calomel, in two pills every four hours, till they act; if not, the croton oil will be the best purgative,

of which one or two drops may be given in sugar or honey every two hours. If these means should fail to restore the action of the bowels, electricity and the sudden application of very cold water to the surface of the abdomen have been recommended. Of the former I cannot adduce any evidence from my own experience, although it would appear to be a most valuable remedy. The latter I have known to succeed.

H. R., a laundress in a gentleman's family, and unmarried, who had long been affected with valvular disease of the heart, was attacked in August, 1850, with sub-acute peritonitis, which was subdued by suitable remedies and by a very profuse hæmorrhage from the nose. On the 11th of September she was seized with severe pain of the abdomen accompanied with constipation and vomiting. As the symptoms were urgent, I was requested to meet her medical attendant from Christchurch, in consultation. I found her suffering severe pain on the left side of the abdomen, a little below the line of the umbilicus, where there was a fulness, painful under pressure. She was frequently sick, and the bowels still were obstructed. Her monthly secretion was present. There was no fever. It was agreed that two grains of calomel and half a grain of opium should be given every two hours, that a glyster (composed of half an ounce of the oil of turpentine, two drachms of the tincture of assafoetida, one ounce of castor oil, and one pint of tepid gruel,) should be thrown up the rectum every four hours, and that six leeches should be applied over the seat of pain. All this was attentively done and various other extemporaneous means tried; but although the pain and vomiting had considerably subsided under this treatment, no relief was obtained from the bowels, which had now been constipated five days. By this time the abdomen had become somewhat inflated, there was hiccup, the pulse flagged, and her recovery was almost despaired of. Her medical attendant, Mr. Davies, supposing that the peristaltic action of the bowel might be suspended by over distension, suddenly dropped upon the abdomen a towel saturated with very cold water, twice following, and then covered it with warm flannel. At the end of an hour the same thing was repeated. This was succeeded by frequent discharges of wind from the rectum, when the inflation subsided, and in a few hours the canal was copiously evacuated. In this case it is probable that the intestine first lost its vermicular power from faecal accumulation, and that it was afterwards still further incapacitated by the pressure of gas evolved from it. Such loss of power, the sudden application of cold in the above ingenious manner, was well calculated to restore, and it appears to have admirably succeeded.

Southampton, April 27, 1852.

[To be continued]

Provincial Medical & Surgical Journal.

WEDNESDAY, JUNE 9, 1852.

At the approaching Anniversary Meeting to be held at Oxford, Dr. COWAN has given notice that he shall propose, that in future the *Journal* shall be published and edited in London, weekly, instead of once a fortnight. Now, we think that so grave an alteration in the mode of conducting this organ of the Association, requires a little calm consideration beforehand, and we have therefore thought it right to place the matter before our readers at once, together with some of the objections which may be adduced to such a change of plan. There can be no doubt that a weekly journal is preferable in every way to a fortnightly one, if the difference of cost can be borne by the funds of the Society; but we can see no way of affording this alteration unless by an increase of subscription, or by the sacrifice of the volume of "Transactions," to both of which courses many of our Associates strongly object; and we are afraid that even Dr. COWAN's eloquence will scarcely convince his hearers of the desirability of the change, unless he can suggest some other means of effecting his object. With regard to the change of place for the publishing and editing the *Journal*, we may not perhaps be considered disinterested advocates, but we have a right to call upon Dr. COWAN to show some advantage to be gained by his proposition, and upon this ground we are ready to join issue, and to maintain in the first place, that it cannot be brought out in London so cheaply, if printed as at Worcester by a general printer, and certainly not so cheaply as it might be done in the country if printed by the Association itself, having its own office, &c., since rent and wages are considerably higher in London than in the provinces.

In a commercial point of view then, we repeat, that we are ready to show that no gain, but rather a loss, would be sustained by the change. Now, as to the Editorial department, it must be borne in mind, that this journal is the organ of a *Provincial* Association, and as such, would lose its distinctive character if conducted by a metropolitan Editor. It never has competed, and never can be made to compete, with the *Lancet* or *Medical Times*, which are purely

commercial speculations, though, like other papers, only remunerative when in accordance with the principles of those to whom they are addressed. Besides, the interests and wishes of the London and provincial practitioners are often at variance—as for instance, in the case of the proposed Incorporation of the General Practitioners, which was advocated by all the London journals, without an exception, and would probably have been carried “*nemine contradicente*,” but for the exertions made in this Journal, prompted as they were by those influential parties in the provinces, who have since so triumphantly proved the truth of their assertions. Again, it is quite manifest that the *Journal* can only be safely conducted in connection with the managing Council of the Association, and therefore Dr. COWAN must also advocate the removal of that management to London, as well as the editorial and publishing departments. We strongly suspect, however, that he is scarcely prepared for this step, of the necessity for which he is perhaps not fully aware.

We have so high a respect for the opinions of Dr. COWAN, that we cannot but think he has forgotten the original object of a journal of the Association. It is quite true, that when first supplied to the members, it was published in London, but an Editorial article was regularly forwarded by Dr. STREETEN, advocating the views of the Association, and even then, though only half the size of the present paper, the cost to the Association, at the rate which only could remunerate the proprietors, was found to be too much for its income. It was therefore determined by the Association to publish a journal which should be devoted to the purposes of forwarding the interests of science in the provinces, by giving insertion to the writings of those medical men, who, while engaged in the toils of country practice, are yet anxious to make known the results of their labours, although not always able to compete in elegance of diction with their London compeers. To many of these writings we could point as equal to anything which has been produced during the same period of time, and we are assured that nothing but health and leisure is wanted to stimulate others to give up the stores of experience with which their brains are teeming, and which would be of more real service than the flimsy effusions of those who write, not to teach others, but to benefit themselves.

Such are some of the reasons which may be

given for adhering to the present mode of conducting this journal, and which should be well considered prior to our annual meeting. We do not for a moment contend that the *Journal*, in its present form, is not capable of improvement, nor do we maintain that it cannot be published weekly; we are ready to co-operate with Dr. COWAN in effecting any improvement, either in the quantity or quality of its composition, but we must raise our voice against its being reduced to a third or fourth-rate London periodical, instead of ranking as it now does, as *sui generis*, without a rival, in its own proper vocation.

Reviews.

Lectures on Clinical Medicine. By Dr. HUGHES BENNETT. No. VI. Edinburgh: Sutherland and Knox.

WE have before had occasion to refer in terms of commendation to the published clinical teaching of Dr. Hughes Bennett. The present number is in every way worthy of its predecessors, and in fact may be taken as a model for bed-side instruction.

The subjects commented upon are certain diseases of the respiratory organs, commencing with laryngitis, and taking in rotation bronchitis, pneumonia, pleuritis, and phthisis pulmonalis.

The chief interest in the author's observations on laryngitis are those in which he refers to the topical treatment of the disease by the actual application of a solution of the nitrate of silver to the interior of the larynx, the demonstrations of which he witnessed at the hands of Dr. Horace Green. Of the value of this treatment he speaks highly.

In illustrating several cases of pneumonia, the lecturer particularly notices the difficulties which occasionally occur, in the diagnosis of the disease. He also gives the following excellent rules for guidance in blood-letting:—

“If you are called to a case at a very early period, before exudation is poured out, and before dulness—as its physical sign—is characterised, but when, notwithstanding there have been rigors, embarrassment of respiration, more or less pain in the side, and commencing crepitation, then bleeding will often cut the disease short. When, on the other hand, there is perfect dulness over the lung, increased vocal resonance, and rusty sputum, then exudation blocks up the air-cells, and can only be got rid of by

that exudation being transformed into pus, and excreted by the natural passages. In such a case bleeding checks the vital powers necessary for these transformations, and as a general rule, if the disease be not fatal, will delay recovery. I believe this to be cause of so much mortality from pneumonia in hospitals, where bleeding is largely practised; for, in general, individuals affected do not enter until the third or fourth day, when the lung is already hepatised.—p. 249.

The author's commentary on the pathology and general treatment of phthisis, is particularly deserving of attention. He considers the disease to originate in an error of primary digestion, leading to an impoverishment of blood, local pulmonary exudations, and those ulterior changes only too familiar to the physician and pathologist. On this view is founded the rational and curative treatment, which the author makes to consist:—1st, in restoring healthy nutrition; 2nd, subduing local irritation; 3rd, avoiding those circumstances which deteriorate the constitution, or induce pulmonary disturbance.

In dilating upon the first of these indications, the lecturer adverts to the present knowledge of the physiology of assimilation, more especially in reference to the part played in the process by the alkaline secretions of the pancreas and other salivary glands. He says:—

“The peculiarity of phthisis, however, is, that an excess of acidity exists in the alimentary canal, whereby the albuminous constituents of the food are rendered easily soluble, while the alkaline secretions of the saliva and of the pancreas, are more than neutralised, and rendered incapable either of transforming the carbonaceous constituents of the vegetable food into oil, or of so preparing fatty matters introduced into the system as to render them easily assimilable. In consequence, more albuminous than fatty matters enter into the blood, and the necessary waste of structure is supplied by absorption of the adipose tissues. In the mean time the lungs become especially liable to local congestion, leading to exudation of an albuminous kind, which is tubercle.”—p. 278.

For the adequate supply of the fatty principle so requisite, cod-liver oil is now well known to be the most efficacious means in our possession, and to Dr. Bennett we are indebted for its first introduction in the treatment of phthisis. We have here a succinct summary of his later experience, in every respect confirmatory of the general impressions regarding its importance as a remedy.

Dr. Bennett is an advocate for the maintenance of the Crystal Palace, (now, and we think rightly, too, in process of demolition,) which he thinks would have been a valuable adjuvant in the prevention and treatment of phthisis, by offering at all times the means of exercise and recreation in a well-regulated atmosphere. Entertaining as we do, however, the notion that climate has very little influence on the disease, seeing that it prevails among the snows of Russia, as well as under the roasting sun of the tropics, we cannot join him in his anticipations.

We hope often to meet Dr. Bennett in labours similar to the present. His remarks always bear the impress of sound practical knowledge, while his great reputation as an histologist gives an authority to his microscopical descriptions, which is not inferior to that of any of his patient fellow-labourers in the Continental schools. Our readers will do well to have these lectures for ready reference.

“*The Beloved Physician:*” a Sermon, preached in the Parish Church of St. Martin-in-the-Fields, on Sunday, March 28th, 1852, in aid of the Funds of the Medical Benevolent College. By the Rev. HENRY MACKENZIE, M.A., Vicar. London: Francis and John Rivington, St. Paul's Church Yard, and Waterloo Place, 1852. 8vo.

WE desire to direct the attention of our readers to this philosophical sermon by the vicar of St. Martin-in-the-Fields, preached on behalf of the Medical Benevolent College, a scheme which must commend itself to the hearty support of every member of our *precarious* profession.

In thus acknowledging our obligations to the vicar for the support he has thus so ably given to this—our great medical charity, we desire to place here on record, his very graceful tribute to the character of the working members of our profession.

“It has now been my lot for many years, to be much connected with the poor of our land in very different localities. I have seen them in deep physical suffering, as well as in spiritual destitution and temporal distress; but in *all* of these cases, I have known none to whom I could turn more readily for aid of any kind than I myself was powerless to afford, than to those whose peculiar province—had they restrained themselves within it—would have limited them to ministering relief to the *physical* ailments of the sufferer. To that point they would necessarily *first* address themselves; but when pecuniary

aid was needed, I have never found their hands closed; and many and many a time I have known *them* to be the first to recommend the sick and suffering to send to their parish priest,—or, it may be, to give him an intimation of their needs that he might call to inquire without their knowing he had been sent for,—and not unfrequently to whisper words of a religious consolation into the ears of those whose days of health had been abused, as though they were to last for ever!

But it is by no means the limited knowledge of personal experience which leads me to advance, and prepares me to uphold, the view that the Beloved Physician—one faithful to his Divine Master, as well as his human brethren—justly represents the character of that profession which fulfils a portion of the direct command of the Saviour, who not only sent out his disciples to “preach the Gospel,” but *also* to “*heal the sick.*” The spiritual-mindedness of a large portion of their body—the religious tendency of a vast number of their publications—the practical faith and personal benevolence so largely practised among them, even to the clear deterioration of their own interests—all point to the same conclusion, and justify our adoption of St. Luke as their type, “Beloved” alike in his divine and in his human relationships.

And if additional testimony were needed to the high Christian and philanthropic character of the class of which I have been speaking, it would be found in that special object which it is my privilege to bring before you to-day.”

As the profits arising from the sale of this sermon will be devoted to the funds of the College, we trust many of our readers may use their efforts to extend its circulation in their respective localities.

Foreign Department.

Iodine Injections in Ascites.

Notices have from time to time appeared in the French journals upon the treatment of ascites by iodine injections, some of which we have transferred to our pages. The chief advocate of the practice is M. Boinet, who has published a long memoir on the subject. (*Gazette Médicale*.) the completion of which has recently appeared. In this concluding paper a *résumé* of his experience is given, from which it appears that he has performed the operation in thirteen cases, eleven of which were successful. No injurious consequences followed the injection in any instance, if we may believe the reports; and one injection was generally sufficient. The deductions with which the author concludes his memoir, are these:

1. That various fluids may be injected into the peritoneum without danger, and with manifest benefit, in the treatment of ascites.

2. That, of these various fluids, the tincture of iodine is indisputably the best, of which an abstract is given in the *Archives Générales*, Mars.

On the Contagion of Secondary Syphilis.

The idea, which now appears to be gaining ground, that secondary syphilis is communicable, has been recently taken up by Dr. Waller, of Prague, in an elaborate memoir. The author herein expresses his conviction, that this form of the disease is contagious, upon the following grounds:—

1. That it is not uncommon to meet with mucous tubercles in persons who have neither had chancre nor gonorrhœa, in whom, in fact, these flat tubercles were the first manifestation of syphilis.

2. That other forms of syphilis, usually denominated secondary, may be the first symptom of the disease.

3. That secondary syphilis may be perpetuated by the agency of the blood.

Several clinical facts are adduced which bear upon these propositions, but we shall pass on to the actual experiment by inoculation, as affording the most conclusive evidence in favour of the author's assumptions.

These experiments were of two kinds; in one series the inoculation was from the secretions of the mucous tubercles, in the other the blood itself was the medium of inoculation.

The first kind of inoculation was performed upon a young man who had never been the subject of chancre or gonorrhœa, by means of punctures on the thigh, to which lint, dipped in the secretion, from a patient labouring under condylomata, was applied; the result was, the production of numerous tubercles upon the site of the punctures. Twenty-seven days after the first appearance of these, syphilitic maculæ began to show themselves on the abdomen, and in a few days more the whole body was covered with them.

The second kind of inoculation was made upon a lad, aged 15, the subject of lupus, who had never had syphilis. On the 27th July some blood was drawn, by cupping, from a female who was labouring under syphilitic maculæ and tubercles, and was immediately applied by means of lint to some scarifications on the thigh of the boy. Neither inflammation nor suppuration ensued, and in three days the incisions were completely healed. On the 31st of August, *i.e.*, twenty-four days after inoculation, two tubercles, the size of a pea, were observed upon the site of the punctures; these increased in size, coalesced, and became covered with thin scales. Eventually ulceration took place. On the 1st of October, sixty-five days after inoculation, and thirty days after the appearance of the tubercles, an eruption, of a distinctly syphilitic tint, came out upon the belly, back, and chest, and speedily became general.

From these experiments the author deduces the following propositions:—

1. Both primary and secondary syphilis are inoculable.

2. Contagion to the testicles of M. Boinet's

secondary phenomena are always preceded by chance, it is established, that in certain cases the symptoms usually considered as secondary, may be the first manifestation of the disease.

3. Neither can we receive, as strictly true, the maxim propounded by M. Ricord, that inoculation furnishes a means of diagnosing primary from secondary syphilis.

Luxation of the Sacrum.

An instance of this very rare accident is reported by M. Foucher, (*Revue Medico-Chirurgicale*), in the case of a man who endeavoured to commit suicide by throwing himself beneath the wheels of a heavily-laden waggon. After death, which occurred at the end of a week, the chief appearance was, a dislocation of the sacrum forwards into the cavity of the pelvis. The ilia were also fractured. Similar cases are on record; one, for instance, in the *Memoires de l'Academie de Chirurgie*, tom. iv., p. 91, in which the accident occurred from the falling of a sack of wheat upon the pelvis; and another is published by M. Laugier, in the *Bulletin de la Societe Anatomique*, Fev., 1850. In some other examples reported the luxation seems to have been the result of disease.

Ligature of the Abdominal Aorta.

This unwarrantable operation has been lately performed by a Portuguese surgeon, who has published the particulars of the case in the *Revue Medico-Chirurgicale* for March, 1852. The disease for which it was undertaken was supposed to be aneurism of the common iliac; the result, as may be readily imagined, was death. A *post-mortem* examination showed that the tumour was, in reality, an aneurism of the external iliac, and that ligature of the upper part of that vessel might have been accomplished.

General Retrospect.

PRACTICAL MEDICINE.

On some Injurious Effects of Tartar Emetic.—By DR. BOLING.

These are thus described:—

The patient may be seen to be doing very well under the antimony, the dulness on percussion and rapidity of pulse diminishing, the skin moistening, and the respiration improving; when, suddenly in some cases, more gradually in others, he becomes restless, thirsty, and somewhat purged, the belly becoming tympanitic, and sometimes tender. He vomits, or tries to do so; the tongue is dry and pointed; jactitation and anxiety of countenance appear, together with delirium, and perhaps shortly before death, stupor. Occasionally jaundice supervenes; and in a few cases the matter ejected closely resembles that of yellow fever. During these occurrences the pulse becomes frequent, hard, small, and thready. Death may take place within six hours after the first appearance of these unfavourable symp-

toms, more frequently it is delayed for ten or twelve hours, and in some cases yet longer.

Simultaneously with the advent of the above symptoms, or just preceding them, there is a more or less rapid disappearance of the symptoms of the original disease. A lung which seemed almost completely solidified, in four or five hours becomes permeable, and yields a healthy respiratory murmur, all the symptoms of the pneumonia undergoing a similar improvement. The violence and rapidity of the abdominal disease are in direct ratio to the suddenness of the improvement in the disease of the lung. In any case of pneumonia treated by antimony, the supervention of the least tympanitis, thirst, and diarrhoea, must be looked upon with suspicion, as the probable precursor of this serious condition; and Dr. Boling regards the patient's doom as almost decided, when, in addition to these symptoms, there is a *rapid*, in place of a *gradual*, diminution of dulness on percussion, *unattended with the crepitant râle of resolution*. The observance of this peculiarity in the physical signs has enabled him to announce portending mischief in patients apparently convalescent.

This cannot be a rare occurrence in the Southern States of America, as the author has seen almost as many die of the induced as of the primary disease. He suspects that some of the cases described as loss of tolerance of antimony by the Italian practitioners, are of this nature, although, if so, their delineation is very incomplete. Gölis gives a graphic account of a similar train of phenomena produced by the use of large doses of calomel in hydrocephalus and cramp.

Dr. Boling is disposed to attribute this effect of antimony to its direct action on the intestinal canal, by reason of a portion of the quantity administered not becoming absorbed; and believes that our object, in attempting its prevention, should be, to administer the drug in such divided doses as to secure its complete absorption. Although never in the habit of giving very large doses, he has even diminished these; and finds the remedy just as efficacious now that he gives only from three to six grains in the twenty-four hours, as when he gave double the quantity, while the mischievous effects have been of much less frequent occurrence. He dissolves the above quantity in six ounces of water, and gives a teaspoonful every half hour in the day, and two teaspoonfuls every hour at night. He prefers water as a vehicle, as mucilaginous fluids delay the absorption of the medicine.—*American Journal of Medical Science*.

Calomel, a Diuretic, in Large Doses.—By Dr. W. KEE.

In the treatment of dropsies, calomel has been considered from its earliest introduction into use as a valuable adjuvant in combination with other remedies, but it is not mentioned by writers as acting as a diuretic when given alone either in small or large doses. Its use in large doses is no new practice, for it has been given freely in the treatment of fever and cholera; and for its hydragogue, cathartic, sialogogue and deobstruent properties, it is well known. In combination with squills, nitre, and sometimes digitalis, it is a very popular mode of administration, and one that generally fulfils the indication for which it is prescribed; but there are cases in which it fails as well as the rest of the class of diuretics, and the physician is thrown back

on his own resources for something more active and reliable. When such is the case, the author affirms that calomel, in doses from forty to a hundred grains, repeated for two or three nights successively, will certainly fulfil the most sanguine hopes, but not only freely purging, but by producing copious diuresis, followed by sleep, such as cannot be had from opium nor its preparations, with safety. During its action, gin or whiskey toddy may be freely used, should there be much prostration; but this is seldom the case, the stimulus only aiding the diuretic action. He states that he has seen persons who were unable to lie down, (for a week at a time,) longer than a few moments, sleep well after the action of the first dose.

His usual mode of administration is to give fifty grains of calomel for three successive nights, and should it fail to produce the desired effect, to wait several days. The first dose does not often act as a diuretic, but the third, according to the author, seldom fails.—*Philadelphia Medical Examiner*, Dec., 1851.

SURGERY.

An Account of a Horn, six inches and three quarters in length, developed upon the Head of a Woman.—By AUSTIN L. SANDS, M.D., of Cold Spring, U.S.

In the spring of 1851 the author was called to see Mrs. W—, aged fifty years. She had always enjoyed good health, and was naturally of a full habit. She informed him that she had a “horn” on the back of her head, which had caused her much trouble and uneasiness for a long time, owing to which circumstance she desired its removal. On removing the covering which she kept continually over it, a fine specimen of ichthyosis cornea, of sixteen years’ growth, was at once brought into view. On inspection, it was found to arise from, or rather immediately over, the occipital protuberance, and to extend downwards and backwards about four inches, and then curling upon itself, terminating in a rough sulcated extremity. On handling it, it was found to be very hard, solid, and, when struck with the handle of a scalpel, gave a sharp clear sound; its attachments to the occiput did not appear to be very firm, as they allowed slight motion. Seeing no difficulty in the way of its immediate removal, an elliptical incision was made on each side of it through the integuments down to the periosteum, and then slipping the scalpel between the base of the horn and the bone, it was easily removed. There was little hæmorrhage, and the wound healed kindly by first intention.

On examination after removal, the horn was found to measure *six inches and three quarters* in length, and *three inches* in circumference at the base.

One very interesting point in the process of this case may be found in the history which she gave of the treatment which had been pursued in order to obtain relief. When first perceived, it felt like a shot underneath the integuments; after some time it made its appearance on the surface of the skin, and several times she picked it off, but after a while it became so firm that she was obliged to allow it to remain. She took no notice of it for some time, but, becoming so large as to interfere with the proper adjustment of her

cap, and obliging her to raise her head from the pillow at night whenever she wished to turn over in bed, while it also incommoded her from reposing on her back, she was necessitated to apply to her family physician (a homœopath) for relief, who promised her that in the space of a short time he would be enabled to remove the difficulty by the use of sundry small white pills, which he proceeded to furnish her with; while at the same time he assured her that he had treated successfully, to a cure, several similar cases within the past year in his own practice. For five years she continued to use the homœopath’s pills, but still the *horn* remained—still the horn continued to grow. In view of this condition of affairs her faith began to falter, but for some time it was supported with the assurance of her physician that the only reason that the cure had not been effected was, “that he had not as yet got hold of the right pills.” Reassured by this assertion, which was repeated from time to time, she kept on until the spring of the present year, when she consulted the reporter, and finally submitted to its removal by the knife.—*New York Journal of Medicine*, November, 1851.

Diagnosis of Fractured Ribs.—By MR. HILTON.

[The following simple rules for diagnosis in cases of suspected fracture of the ribs, offered in a clinical lecture upon the subject, delivered at Guy’s Hospital. In such cases Mr. Hilton observes:—

1. There may be external ecchymosis, but this symptom may be entirely absent.
2. Sharp pain in a determinate locality on full inspiration; this pain is sometimes intense, and the constancy with which it is met with in different cases gives much importance to the symptom. The pain is caused by the compression of the intercostal nerve at the ends of the fractured rib on a strong inspiration, ordinary breathing giving little or no uneasiness; according as the direction of the fracture leads to the compression of the nerve, or to no such structural complication, so will there be more or less pain. Hence the reason why some patients suffer a great deal, and others but little pain. This association of pain is not peculiar to rib fractures. The same thing occurs in fracture of the anatomical neck of the humerus, which lesion may and does frequently cause compression and irritation of the circumflex nerve; the latter being forcibly caught or drawn between the fractured ends of the bone, produces intense pain at the part.
3. By placing your hand upon the sternum, you may feel crepitation as the breathing goes on—nay, the patient sometimes hears and feels it himself.
4. Great tenderness over a certain suspected spot is a symptom upon which great reliance cannot be placed. It is better to press forcibly upon one rib after the other near the sternum, during inspiration, from above downwards. With some attention you will thus be able to detect the broken rib by resisting the elevation of its sternal end whilst its vertebral extremity is in motion, and a further examination of the individual rib discovers the exact seat of the fracture.
5. You may be much assisted in your diagnosis by using auscultation, either with the stethoscope or the naked ear; the fine grating of the bones may sometimes be distinctly heard in this manner. But, if in spite of careful examination, you cannot find any or all these symptoms, remember that

it is far better to treat obscure and doubtful cases as if fracture of the ribs had been detected; you will err, if at all, on the safe side, and the therapeutical means necessary are so simple that you cannot possibly do your patient any harm.—*Lancet*, March 13, 1852.

MIDWIFERY.

Abscess of the Substance of the Uterus, opening externally.—By Dr. VAN COURTLAND.

On the 27th of June, 1830, the author was sent for to see W. M., aged 24 years, who told him she had been delivered of a living child about two months previous, but had never left her bed, owing to a swelling in the lower part of her belly, and which began to show itself a few days after her confinement. The patient was emaciated to a most extreme degree, and was labouring under profuse and almost uninterrupted perspiration. The pulse was small and rapid. The countenance indicative of serious disorganization. The secretion of milk was entirely suspended. The lochial discharge had left her a few days after parturition; and the spirits were painfully depressed. On examining the swelling, owing to the great emaciation, he readily discovered it to depend upon an abscess of the body of the uterus; adhesion between which and the abdominal parietes had taken place during the inflammatory state, and the abscess now in progress clearly indicated the plan of treatment to be adopted.

Large doses of diluted sulphuric acid were given without producing diarrhoea, warm fomentations and emollient pulvices were applied to the tumour, and frequently renewed until the 8th of July, when a free opening gave vent to about half a teacupful of matter. From this time, everything went on well, and in a few days she returned home cured. Her catamenia have come on regularly, but as yet she has not again become pregnant.

In cases of this description, the discharge of matter almost invariably takes place by opening internally either into the bladder, rectum, or vagina.—*Canada Medical Journal*. No. I.

Correspondence.

THE NEW CHARTER OF THE COLLEGE OF PHYSICIANS.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I have just seen in the last number of our *Provincial Medical and Surgical Journal* an abstract of the proposed new Charter of the Royal College of Physicians.

There are two clauses, namely the fourth and fifth, which appear to me to call loudly for animadversion, as their obvious effect will be to do great injustice to a very numerous and very respectable class of British physicians—the Extra-urbem Licentiates.

The fourth clause enacts, that all such shall become

"members" of the College, on presenting satisfactory testimonials of character, and on paying a fee of fifteen guineas, exclusive of stamp duty.

Is it not humiliating and affronting thus to be desired by the College to bring *testimonials of character*, when we have already one emanating from the College itself, and attested by the President and Elects? They have already certified each individual Extra-urbem Licentiate as "probum virum, eumque dignum judicasse qui admittetur ad praxin." Is this insufficient and unsatisfactory? And are we to go to members of our own profession (our juniors perhaps by many years), and ask them to say if we are *honest* and *sober*, and *fit* to practise our profession?

Again, I object to being compelled to make another payment of £20 or £30, (which it would be with stamp duty,) without some equivalent advantage.

We, the Extra-urbem Licentiates, have been examined by the College;—we have received their letters-testimonial of character and skill;—we have paid pretty handsomely for any little advantage which the licence of the College confers (and be it remembered that one half of the physicians of the country practise without it); and now, after all this, we are to be *disfranchised*, and our dearly-purchased piece of parchment is to become merely so much *sheep-skin*.

We have the opinion of Sir Fitzroy Kelly, formerly Solicitor-General, and Sir E. V. Williams, that there is no just reason for making any distinction (in any future Charter) between the privileges to be conferred upon the Intra and Extra-urbem Licentiates. But, instead of this, the former are at once translated in a body, without question asked or money paid, into "members" of the new College, whilst the claims of the latter are ignored; and although their names have been printed in the College lists, they are no longer deemed worthy to belong to the College without further testing as to character, and a little more pecuniary depletion.

Let us now consider the fifth clause. All graduates of recognised Universities are at once to be admitted *members* of the College, on producing certificates, and paying the customary fees. Had this been done some ten or fifteen years ago it had been fair and honourable; but now several hundred graduates have already undergone an examination, and paid for what they thought admission into the College, and then comes a new bar, which renders nugatory all which they have done to connect themselves legally with the College. Those who have defied its laws all their professional lives, and kept their money in their pockets, may now be admitted on equal terms with those who considered themselves as already belonging to the College.

I trust that those who think—with the writer of these lines—that a grievous act of injustice is about to be done to the ill-used Extra-urbem Licentiates, will come boldly forward and make their sentiments known in the right quarters. If so, I verily believe we shall gain redress.

If the Extra Licentiates choose to move from the provinces and fix themselves in London or its vicinity, I do not think they would object to a farther payment to the College, as has been done by the Intra-urbem Licentiates; but, to make no difference in any respect,

between those who are already, and those who never have been, connected with the College, is manifestly unjust, and unworthy of any learned body.

Since I began my letter I have been much pleased by seeing a letter in the "*Medical Times and Gazette*," having a similar object.

I am, Mr. Editor,

Your obedient Servant,

May, 1852.

M.D., EDIN.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—We are directed by the Committee of the Manchester Medico-Ethical Association to request the publication of the enclosed in the next number of the *Provincial Medical and Surgical Journal*.

We are, Sir, your obedient Servants,

J. AIKENHEAD, } Hon. Secretaries.
W. C. WILLIAMSON, }

Manchester, May 28, 1852.

To the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled.

The Petition of the undersigned members of the medical profession, on behalf of the Medico-Ethical Association, of Manchester, humbly sheweth,—

That the provisions of a "Bill for Regulating the Qualifications of Pharmaceutical Chemists" have been brought under the notice of your petitioners.

That your petitioners, whilst approving of the spirit in which this measure is framed, believe that there is some danger, owing to the present unsettled and unsatisfactory relations between members of the medical profession and pharmaceutical chemists, of the latter interfering with their rights and privileges.

That your petitioners would therefore humbly pray your Honourable House to insert a clause in the Bill that nothing therein contained shall be understood to confer on chemists any right to practise medicine in any of its departments whatever.

And your petitioners will ever pray, &c.

W. J. WILSON, F.R.C.S.E., Vice-President.

J. AIKENHEAD, M.D., } Hon. Secretaries.
W. C. WILLIAMSON, }

Medical Intelligence.

MUNIFICENT BEQUESTS.

The Devon and Exeter Hospital has recently had two munificent donations added to its funds—one of £2,000, left by the Rev. Dr. Troyte, late of Huntsham, and the other by the late Mrs. Halford, of Newcourt, near Exeter, who (after giving specific legacies amounting to £60,000) has bequeathed the whole residue of her property to this institution, which will amount, it is said, to nearly £50,000, £20,000 of which will be available on the death of the husband of the testatrix, who has a life interest in it.

PRESENT TO THE ROYAL COLLEGE OF SURGEONS.

Mr. Abbott Lawrence, the United States Minister at this Court, having stated to the Lords Commissioners

of Her Majesty's Treasury that two cases have arrived from New York, addressed to him, and containing fossils, sent by Dr. John C. Warren, of Boston, United States, for presentation to the Royal College of Surgeons, London, their Lordships have given the necessary directions to the proper authorities to permit their free delivery for that purpose. Dr. Warren is an Honorary Corresponding Member of the Provincial Medical and Surgical Association.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 21st ultimo:—Henry Vandyke Carter, Scarborough, Yorkshire; Thomas Boor Crosby, Gosberton, Lincolnshire; Robert Anlezark Cunliffe, Garstang, Lancashire; Samuel Athanasius Cusack, Dublin; Maurice Davis, Thame, Oxfordshire; Samuel Foley, Army; Thomas Frost, Hucknall-Torkard, Nottinghamshire; Michael Hurley, Dublin; Robert Benson Lewis, Trinity Square, Southwark; William Edward Musson, Birkholme, Lincolnshire; Andrew Nesbitt Edwards Riddell, Ayr, East Indies; Augustus Charles Shout, Hampstead.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on the 20th ultimo:—Barnabas Barnett, Shrewsbury; Thomas Croudace, Chester-le-Street; William George Gill, London; Alfred Richardson, London; George Sankey, Ashford; John Sykes, London; Alfred Stephen Wood, London.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

YORKSHIRE BRANCH MEETING.

The annual meeting of this Branch will be held at the Medical School, Leeds, on Thursday, June 10th, under the Presidency of C. Chadwick, M.D. The chair will be taken at one o'clock precisely. The members and visitors will dine together after the meeting.

WM. MATTERSON, JUN.,

Hon. Secretary and Treasurer.

York, May 21, 1852.

NORTH-WALES BRANCH.

The annual meeting of the North-Wales Branch of the Provincial Medical and Surgical Association, will be held at the Castle Hotel, Conway, on Tuesday, the 15th of June, at eleven o'clock.

DR. EDWARD HUGHES, of Mold, President.

LANCASHIRE AND CHESHIRE BRANCH.

The Sixteenth annual meeting of this Branch will be held on Wednesday, the 30th of June, in the Medical Institution, Mount Pleasant, Liverpool. The chair will be taken at one o'clock by Robert Bickersteth, Esq., of Liverpool, the President for the ensuing year. Dinner will be provided at the Adelphi Hotel, at four o'clock, for such members as intimate to the Secretary their intention of being present.

JOHN HATTON, Hon. Sec.

114, Oxford Street, Manchester.

TO CORRESPONDENTS.

Communications have been received from Dr. Tilt, Mr. Grainger, Nil Desperandum, Dr. Speer, Medicus, Mr. Terry, Mr. Perceval (twice), Mr. Churchill.

MEDICAL BENEVOLENT COLLEGE.

PRESIDENT.

THE RIGHT HONOURABLE THE EARL MANVERS.

TRUSTEES.

DR. J. A. WILSON.

DR. R. LEE, F.R.S.

W. FERGUSSON, Esq., F.R.S.

JOHN BACOT, Esq.

BENJAMIN PHILLIPS, Esq., F.R.S.

TREASURER.

JOHN PROPERT, Esq., 6, New Cavendish Street.

THE COUNCIL, in announcing the FOURTH LIST OF CONTRIBUTORS to this truly national undertaking, beg most cordially to congratulate the Profession on the unexampled success that has attended their labours. In the short space of eleven months, nearly £10,000 (of which £1000 are annual subscriptions) have been contributed towards establishing a "haven of repose" for those who, as instruments in the hands of an All-wise Providence, have laboured incessantly in assuaging the sufferings of their fellow-creatures. Surely, with such a manifestation of general co-operation, there can no longer exist any doubt in the minds of those who have hitherto withheld their support from a belief that the attempt to establish this eleemosynary retreat would not be successful.

The Council gladly avail themselves of this opportunity to again gratefully acknowledge the most efficient and important services rendered by those who have nobly stepped forward both in London and the provinces, to aid in this "labour of love," and they earnestly entreat the cordial assistance of every Practitioner throughout the kingdom to enable them to accomplish the desired object they have in view. In order to show the great good that might be effected by little means, it may be stated, that if every Member of the Profession were to contribute, or to collect the small sum of £5 in aid of the Funds, the Building necessary for this noble Institution, would not only be speedily raised, but the College itself also most liberally endowed.

As there exists an erroneous impression in the minds of some kind benefactors to the College,—viz., that as a Chapel is to be provided for Divine Worship according to the principles of the Church of England, those of a different persuasion would be compelled to attend it against their inclination, the Council think it right distinctly to state, that the Pensioners will be at perfect liberty to worship their Maker in the way most consonant with their religious feelings.

Donors of *Ten Guineas*, and upwards, will be *Life-Governors* of the College; also, Collectors of *Twenty Guineas*, paid to the College in one sum.

HONORARY LOCAL SECRETARIES.

ON THE
DIAGNOSIS OF CHRONIC OVARIAN
TUMOURS.

By E. J. TILT, M.D.,

Senior Physician to the Farringdon General Dispensary and Lying-in Charity, and to the Paddington Free Dispensary for Diseases of Women and Children.

"Hydrops ovariorum ut plurimum steriles annosaeque mulieres occupat difficulter cognoscitur et vix sine sectio cadavere."—Boerhaave (*Aph.* 1223.)

At different times we have published, in the *Lancet* and in the *London Medical Gazette*, a series of papers on the "Pathological Anatomy of Chronic Ovarian Growths, and on their Cause, Progress, and Termination." We now purpose treating of the diagnosis of these tumours, and feel no little hesitation in beginning a chapter which must be the history of the mistakes daily committed, even by the most enlightened.

The difficulties of the diagnosis of chronic ovarian tumours arise from the form and nature of the cavity in which the abdominal viscera are contained. The more easily defined limits of other organs render the diagnosis of these diseases comparatively easy; but it was necessary, for the health of the body, and to economise the space allotted to the abdominal viscera, that they should have no fixed limits, in order that they might, in their periodical ebb and flow, appropriate each according to its peculiar wants more or less of the same cavity. This community of habitation entails a certain obscurity of position, and gives rise to a corresponding obscurity of diagnosis of the diseases of the abdominal organs. With other organs we find that any obscurity of diagnosis which might have existed in the origin, diminishes as the disease progresses, but the certainty of the diagnosis of ovarian tumours does not increase in proportion to their dimensions, because each of the neighbouring viscera—womb, liver, spleen, kidney, and bladder, are susceptible of attaining to a similar bulk, and these organs must, therefore, be believed to be in a healthy state by the medical attendant, before he can diagnose an ovarian tumour.

Another difficulty of abdominal diagnosis arises from the fact, that the abdominal cavity, more than any other, harbours not unfrequently tumours of stupendous size, which have no other origin than some minute sub-peritoneal cell. In such cases we need not be surprised that a tumour, which belongs to no organ, should be, by different medical men, attributed in turn to a swelling of each of the abdominal organs in the vicinity of which it is developed.

It may be thought that we exaggerate the uncertainty of abdominal diagnosis, but we do not hesitate to say that it is more difficult to diagnose many complaints of the organs contained in this cavity than those of the chest or the head. Medical men have sometimes brought us patients said to be affected with ovarian dropsy, but who were in reality suffering from fibrous tumours of the womb, chronic peritonitis, or even *embonpoint*,

particularly when the patients have arrived at the age of cessation of menstruation. All those who are engaged in active practice must be able to recal similar proofs of the great imperfection of abdominal diagnosis, and the operations of ovariectomy furnish us with wholesale examples of the errors of diagnosis made by the most eminent in our profession; errors made by men who have specially studied ovarian disease, and the individual cases of that disease which they attempted to cure radically by an operation, on the value of which they staked their medical reputation. Dr. Dolhoff, at Magdebourg, had studied his patient's case for a year; many eminent men who had seen the patient with him were convinced of the existence of a tumour, and still none was found when the abdomen was opened. The best opinions of Edinburgh confirmed Lizars in his opinion, that a patient of his was affected with an ovarian tumour. An operation was performed, but no tumour was found. We learn from Dr. Atlee's valuable table, that out of 179 cases of attempted ovariectomy, the operation could not be completed in 34. This means in plain English, that in 34 out of the 179 the surgeons made an unfortunate error of diagnosis. In 17 of these cases other important diseases existed, which would have contraindicated ovariectomy, but as these were not detected by the surgeon, the 17 operations were performed, and occasioned the death of 14 of the patients. Adhesions of the tumours to neighbouring organs are also considerable complications when they are extensive, as was the case in 62 operations out of the above-mentioned 179. In other words, these 62 cases were also errors in diagnosis; for if the surgeon had suspected the existence of these adhesions, he would, in most of the cases, have declined operating, well knowing that this complication increased the difficulties of the operation, increased the ratio of its mortality, and sometimes rendered it impossible. In six cases, says Dr. Atlee, (but two others are recorded,) no tumour was found, so that in these patients the abdomen was opened, it was examined for a tumour, and none was found, and then the abdomen was sewn up. The 179 operations of ovariectomy thus afford us proof of 121 errors of diagnosis, and justify the motto placed at the head of this chapter.

While, however, admitting the imperfection of our diagnosis of abdominal diseases, we must not omit mentioning that some of our means of diagnosis have lately been improved, and that others have recently been added, which, if judiciously used, permit us to anticipate a diminution of what has been well termed "ovarian perplexities."

In Professor Piörny's hands Avenbrugger's discovery has been proved to be equally serviceable in detecting diseases of the abdomen as those of the thorax. Kergaredeo applied his uncle's stethoscope to the abdomen, and taught us to distinguish a sound, by which, if distinctly heard, we can be confident of pregnancy. And later still, the head of the obstetric department of our profession in Scotland, Dr. Simpson has given us a very important instrument of diagnosis—the uterine sound, by means of which we are generally

able to eliminate the uterine element from very complicated problems of abdominal morbid structure. This instrument has indeed been inveighed against, with considerable force, by some who have been peculiarly struck by cases wherein the instrument was injudiciously employed, but as a help to diagnose abdominal disease, it is undoubtedly of great utility, a conviction expressed with the greater pleasure, because we differ in some other points of practice with its illustrious inventor.

Having shown the difficulties of abdominal diagnosis, having pointed out the reason of these difficulties, and glanced at some of the means by which they may be diminished, we shall now proceed systematically in our attempt to unravel the obscurity which we deplore. Our idea of diagnosis is to distinguish some peculiar disease from all those with which it may be confounded, we shall then proceed to pass in review, one after the other, all the diseased organs with which ovarian tumours have been confounded, or, in other words, all the abdominal viscera.

Should the reader find that we are tedious in the inquiry, let him remember that in learning to detect ovarian tumours he unavoidably learns to discover the other tumours or diseases of the structure which so frequently occur in the abdomen, and that he will thus acquire a knowledge of abdominal disease, the obscurest and the most important part of medical diagnosis, for the viscera of nutrition are those principally affected in all diseases. Let him remember that the rarity of any peculiar disease should not be an unconquerable obstacle to the sagacity of the practitioner, who knows how to seek for the signs of disease and how to interpret them. Acquainted with the anatomy of the visceral organs, and conversant with their functions, the medical attendant should be ready to interpret those rare cases which, in the course of practice, may perhaps "turn up" to-morrow.

Chronic ovarian tumours have been confounded with ovaritis, on account of the extraordinary size of the acutely-inflamed ovary, but the rapidity of the development of the tumour, and the fever by which it is attended will not permit the practitioner to be easily deceived; and the rapidity of the march of the disease will soon show the disease to be acute. On account of the acute march of an ovarian cyst, it may, however, be confounded with ovaritis. In the *London Medical Gazette* we have related an interesting example of this; the fever was such as attends acute disease, the iliac pain was intense, the swelling rapid, and we should have remained convinced that the tumour was of a purulent nature, if an exploratory puncture had not been made, and a transparent albuminous fluid withdrawn. A careful examination of the patient could alone prove that, in such cases, the ovary is affected, the knowledge of the nature of the tumour being left to be determined by the subsequent history of the case, a delay little to be regretted, as in both cases the indications would be the same, that is to say, to arrest the progress of inflammation by bloodletting and mercury. Ovarian tumours have been confounded with pelvic tumours, sanguineous or purulent, developed in the recto-vaginal pouch. By means of the uterine sound it is easy to eliminate the

uterus from the morbid problem, but it is sometimes difficult to distinguish an incipient ovarian from a pelvic tumour, in cases similar to those described by Dr. Seymour, where the falling of the ovarian tumour into the recto-vaginal pouch gives rise to excessive pain. A few days will generally suffice to clear up the difficulties of diagnosis, for while the distressing symptoms attendant on the position of the tumour diminish, or at least do not increase, the constitutional symptoms will increase if the tumour be purulent, and it will most likely point towards the vagina, the rectum, or the skin, in the inguinal region. In very rare cases, however, it may happen that a purulent tumour attains a large size in the recto-vaginal pouch, without the difficulty of diagnosis being diminished, as when they imitate those ovarian tumours which are quite round, central, painful, and bulge into the vagina. In a very interesting case, recorded at great length, by Dr. Camus, (*Revue Médicale*, 1838,) the patient would certainly have been considered to be suffering from ovarian dropsy if it had not been known that the disease originated in the culpable introduction of an instrument into the womb to procure abortion. The tumour took several months to attain the umbilicus. In this case an obscurity in the diagnosis was not much to be regretted as it did not increase the difficulty of the treatment. The indications were similar in the event of either disease, and a vaginal puncture of the bulging portion which did cure the abscess, might also have radically cured the ovarian cyst, as has happened in many an instance.

Sanguineous pelvic tumours are more likely to be confounded with incipient ovarian tumours, and as they have not been described by classic authors and have been but lately investigated by French pathologists, it may be well to glance at their history. In the midst of menstrual disorders, consisting in the flow being more or less abundant and painful than usual, intense hypogastric pain arises with fever, which last a few days, then ensues a dull heavy bearing down pain in the hypogastric region, and a large collection of blood forms in the recto-vaginal pouch, which, by pressing the rectum in and against the concavity of the sacrum, gives rise to obstinate constipation, whilst by pressing the urethra against the pubes, the same tumour causes a difficulty or impossibility of passing water. At first fluctuation may be easily detected in this tumour, but when the blood coagulates it becomes hard, and in one instance was mistaken by Malgaigne for a fibrous tumour of the womb. The tumour often disappears by resolution, or else it may open and discharge its contents in the vagina or the rectum.

These details are sufficient to show that when ovarian cysts are so confined by false membranes, as to be developed in the recto-vaginal pouch, it may be difficult to distinguish them from sanguineous pelvic tumours, but the more rapid growth of the latter and their early fluctuation, enable the practitioner to form a correct opinion, and time will give certainty to the diagnosis.

11, York Street, Portman Square.

REMARKS ON THE TREATMENT OF BURNS AND SCALDS.

By W. J. MOORE, Esq.,

Resident Surgeon to the Queen's Hospital, Birmingham.

THE satisfactory termination of a burn or scald will often depend on the mode of treatment adopted when the patient is first brought under the care of the surgeon, not only as regards the constitutional measures taken, but also the external applications then had recourse to. The numerous dressings which, from time to time, have had their advocates, undoubtedly act much in the same manner—preventing exposure to the atmosphere; but from their plurality it becomes somewhat difficult to make a selection of that most appropriate, especially as many are recommended, backed by an equality of testimony and evidence. In making such selection, guidance should be taken, not from the reputation which such and such an application may happen to possess, but rather from the characters of the burn itself, injuries of a moderate nature requiring different, and perhaps more careful treatment in the first instance, than those of a more severe description.

Probably few things are more distressing, both to the witnesses and the sufferers, than cases of bad burns; and this remark is not only applicable to the time when the burnt part is undergoing cicatrization, but tells with double force when, from contractions and loss of integument, an eye is rendered almost useless, a limb becomes an absolute incumbrance, or the chest and chin unite. Happily such cases are now rare; but frequently, and notwithstanding the greatest care, some approach to such a state is inevitable; it is, therefore, of consequence that any treatment tending to obviate these unpleasant results should be propagated and made known as universally as possible.

Nearly three years back Dr. Steward, who was at that time my colleague in this institution, first recommended and brought into practice the use of creasote oil as an application to burns and scalds. I at that time bore testimony to Dr. Steward's estimate of its worth, and gave in one of the periodicals my opinion of its mode of operation when employed in such cases. Subsequent experience, without diminishing my faith in its efficacy as an application, has, however, led me to use it only in a certain class of cases; and the same experience has also led me to make use of other applications, which perhaps I may feel justified in recommending to notice.

Of course a burn or scald denotes inflammation, which inflammation is followed by its necessary consequences, precisely as though set up by a totally different cause; the first indication, therefore, is to keep down such action, and limit the mischief which may probably arise. And for a very slight burn or scald this object cannot be better fulfilled than by the constant employment of cold; and as an application in such a state nothing can be better than water, to which

a small quantity of æther or spirit has been added; or otherwise a piece of metal—brass or lead—will be found a very convenient substitute. This plan of treatment, however, will not do if much of the surface be injured, and it then becomes necessary to use an application which will both afford some degree of stimulus to the part, and aid in relieving congestion of internal organs. Such an application presents itself in creasote oil, and it is in burns of this description where its use is most successful.

Supposing a person to have the misfortune to burn some part, say, for instance, the forearm and hands; supposing the burn to be of that character which may be said to partake of the first and second degree of intensity, having several blisters already formed, I should recommend, and have practised with great success, the following treatment:—Any vesicles present are to be first punctured, and the parts then dressed over with creasote oil by means of a feather or brush, and allowed to remain exposed a short time. This generally has the effect of immediately relieving the pain, which perhaps may be due to the coagulation of the albumen contained in the serum thrown out, by the creasote; which fact is rendered apparent by the formation of a white film wherever the oil touches the abraded surface. It thus prevents the contact of the air. A minute or two having elapsed the dressings should be repeated, and the whole parts (if the hands) enveloped in strips of linen, slightly oiled, with a bandage over all, for better security of the dressings. In such a case as the one supposed, the cure will be complete in two or three dressings; and it is well worthy of notice, that if the creasote oil is applied soon after the receipt of the burn, it will effectually prevent any large amount of vesication.

I have recommended envelopment in oiled linen after the application of the creasote, on account of the situation of the parts supposed to be injured, but the effect is equal, and in some cases more marked, when no other application whatever, excepting the creasote oil, is used. Should the leg be the part burned, and the patient be able to lie by for some time, I should not use anything except the creasote; either preventing contact of the clothes by means of a cradle, (if the patient, as is the case in a hospital, can be made to lie in bed,) or otherwise by means of a sort of funnel, composed of cane hoops and linen, easily adapted round the limb. The application of the creasote should then be performed twice a day. The parts where there are no vesications are well at the second dressing, and the vesicated parts become covered with coagulated serum, which forms a scab, and makes the best protection which can by any possibility be devised. The cure is thereby rendered easy, painless, certain, and without smell, and the scab in a short time becomes detached from the newly-healed surface. I have treated large portions of the leg, thigh, and body in this way, the scabs formed gradually shelling off from the circumference inwards; but of course it is always proper to prevent, if possible, the loss of the cuticle, which is very liable to be rubbed off during conveyance to a

hospital, removal of clothes, &c. This treatment is peculiarly applicable to burns of the face where there is difficulty in retaining any dressing. The oil, however, may easily be applied, the only care requisite being that it does not enter the eyes, as from its stimulating properties it would cause great pain, and perhaps some degree of inflammation; should this accident happen, it is best to bathe the eye immediately with a little water. Many persons have expressed to me their fears for the consequences of not covering the parts, otherwise than by the creasote, particularly when, as sometimes happens, the patient is obliged to go out into the open air immediately afterwards; more covering, however, is not at all necessary. Burnt faces frequently are dressed and sent away exposed, and without any bad results. One case particularly intrudes itself into my recollection, which strongly illustrates this fact:—

A man applied during the winter of 1849, having his face burnt by an explosion of gunpowder. He was dressed with creasote, and taken into the ward; he, however, would not stop, and starting off home walked a distance upwards of four miles, there being at the time a high and bitterly cold wind. When he presented himself next morning he stated he had felt no pain from the exposure, the film of coagulation having effectually acted as a preservative against the piercing blasts. He continued his visits to the hospital until cured, and was exposed in like manner every day.

I trust enough has been said to prove there is some efficacy in this mode of treatment, and should any feel disposed to give it a trial, I fancy they will not be disappointed regarding the results.

I occasionally, however, treat burns in a different manner, but, as I said before, am regulated in my application by the character of the injury. A very good plan is to apply a thick solution of gum, allowing it to dry on the parts, which it speedily does, forming a kind of mail coat, which also acts effectually as a preservative from the atmosphere. This, when dry, cracks, and in a few days peels off, leaving the parts more or less healed. This is a very good mode of treatment when the smell of creasote is strongly objected to, which idiosyncrasy is sometimes met with.

Another very good application, and one which I can recommend, is an ointment, containing a proportion of hydrocyanic acid, or rather, more properly speaking, a liniment; my application being composed of olive oil, hydrocyanic acid, and *fresh* lard. The value of the application evidently consists in the hydrocyanic acid allaying the pain, which it does to a great degree. Probably the virtue of the famous quack remedy—the laurel ointment, depends on the same cause.

When called upon to treat burns of the third degree, where sloughing and loss of substance is inevitable, as it matters but little what application is made use of in the first instance, I generally smear the parts with some oily material, or carron oil, if procurable, and then envelop them in a *flannel* roller. This is allowed to remain for some days, until suppuration has commenced, when it is removed, and either a poultice or lint, soaked in lukewarm water, used in its stead. The

ulcers which result, of course must be dealt with according to approved surgical principles, but they will be, under any treatment, sufficiently troublesome. The chief point is to repress the exuberance of the granulations, which tend to render the cicatrix unsightly, and also retard that desirable process; while padding and splintering must also be kept in view, to prevent the lamentable contractions so disposed to take place. I may here also observe, that consistent with cleanliness, the less frequently a burn is *dressed*, the more likely will the patient be to progress favourably, as frequent exposures are thereby avoided. And I also am persuaded, that when a large surface has suffered, only a part of that surface should be exposed at one time; *nimia diligentia* in the treatment of burns is thoroughly deprecated.

Not the least difficult part in the management of a case is the internal treatment, when a burn or scald is of a severe description. The shock to the system is exhibited by the shivering, paleness, weak pulse, or perhaps stupor, present, and imperatively calls for brandy, wine, or other stimulants. In slighter cases, however, warmth to the feet, and a little warm tea only are requisite. Perhaps the most danger, particularly in children, occurs about the fourth day, when the lungs frequently become congested and difficulty of breathing results. Antiphlogistic treatment must then be adopted and leeches applied to the spine, with antimony internally, perhaps combined with compound tincture of cardamoms or sulphuric æther. It is believed several lives have been saved by this treatment, which would have been sacrificed had stimulants been altogether persevered with as frequently advised.

There is one drug which is frequently recommended in burns, viz., opium, but it is for the most part unadvisable, adding as it does to the congestion and stupor already present; the only time when it appears to be proper, is when diarrhoea has supervened, when it frequently produces great comfort and is evidently productive of good. Hyoscyamus is the preferable drug, should a sedative be wished for in these cases.

[To be continued.]

CASE OF LOOSE CARTILAGES IN THE KNEE-JOINT.

By THOMAS T. GRIFFITH, Esq.,

SURGEON TO THE INFIRMARY WREXHAM.

FEW local ailments unattended with continued inflammation, occasion so much pain and inconvenience as loose cartilages in the knee-joint. Therefore persons dependent on active exertion for their livelihood, and others who may be anxious to be at once freed from the complaint, have from time to time submitted to the operation for their removal, and though this has generally been successful, yet it has not unfrequently been followed by violent "inflammation,* fever, and

* Vide "Medico-Chirurgical Transactions," vol. xiv., page 277, and Cooper's "Surgical Dictionary." Article—"Loose Cartilages in Joints."

death." As a substitute for so grave an alternative, Mr. Key, in his valuable work "On Practical Surgery," recommended the continued use of a "well-adapted knee-cap, and which produced a cure in some cases recorded by him. But in other cases the effects were merely palliative and only to be secured by a perpetual use of the knee-cap. Cooper, in the seventh edition, (page 850,) of his "Surgical Dictionary," offers little hope from any other treatment, than that of excision. He says:—"If we except an incision into the joint for the purpose of extracting these cartilaginous formations, we are not acquainted with any certain means of freeing a patient from the inconvenience of the complaint."

The successful issue of the following case induces me to record it with the hope that others will give the same mode of treatment a trial, and if from further experiments it shall be found productive of the same results, then another safe means may be offered the patient of avoiding the dangers attendant upon incisions into the large joints. It is probable that the different results from the same mode of treatment will be found to depend upon the greater or less predominance of osseous or cartilaginous matter in these substances. But as this cannot be determined before hand, it will of course be right to propose to the patient the advantage of a safe and mild course of treatment, before subjecting him to an operation uncertain in its effects on health and life itself.

A. B., a healthy young woman, aged 22, acting as housemaid in a gentleman's family, applied to me in April-1851, on account of a violent pain, occasionally felt in the left knee-joint. It had existed for some time, but becoming worse and more frequent she could barely perform her ordinary duties. I found a substance of an oval form, rather less than a flattened sparrow's egg, lying on the inner side of the ligamentum patellæ, and in front of the semilunar cartilage. It was moveable but could not be forced into the cavity of the joint; pressure gave considerable pain; ordinarily the knee was free from pain. I began the treatment by strapping and bandaging the joint, avoiding direct pressure over the substance. This plan afforded so little relief, and the frequent returns of pain so much interfered with her duties that the necessity for an operation was considered. To avoid this extreme measure I tried the effects of increasing the action of the absorbents by blisters repeated every two or three weeks, and by friction in the intervals with compound iodine ointment. Under this treatment, the substance lessened and became small enough to slip frequently between the articular surfaces, causing intolerable pain and the risk of suddenly falling down. Absorption continued, and at the end of about nine months the patient ceased to feel pain or inconvenience; and now, (May 25th, 1852,) I can discover no remains of loose cartilage. With the exception of some irregularity in menstruation, which yielded to a short course of iodide of iron, her health has been perfectly good, nor have any unpleasant effects followed the long-continued use of the iodine ointment.

Wrexham, May, 1852.

THE
LIFE OF THE BLOOD, AS VIEWED IN
THE LIGHT OF POPULAR BELIEF.

FROM

NOTES OF AN INTRODUCTORY LECTURE DELIVERED
BY THE PROFESSOR OF GENERAL PATHOLOGY IN THE
FACULTY OF MEDICINE OF MONTPELLIER.*

By STANHOPE TEMPLEMAN SPEER, M.D.,
CHELTENHAM.

THE next singular proof of the belief in the life of the blood, entertained more especially during the middle ages, is to be found in the superstitious notion that when an individual had been murdered, his blood would begin to flow afresh at the sight of the murderer, demanding as it were justice and revenge.

The origin of this belief appears undetermined. We know neither the people among whom it took its rise, nor the period at which it became general. This, however, we know, that in the twelfth century it was one of many other superstitions, founded upon a misconception of certain natural phenomena, and was considered worthy of implicit confidence.

In 1189 Henry II., of England, died at Chinon, in Touraine, and was conveyed, according to his previously expressed wish, to Fontevrault. The body was lying in the Church of the Abbey, waiting for interment, when Richard, afterwards Cœur de Lion, arrived. On entering the Church and approaching his father's coffin, he perceived that his countenance was contracted, and gave evidence of a painful death. Richard shuddered at this spectacle, remembering all the wrongs he had done his father, and the opposition he had ever made to him. He knelt at the altar, and the historians of the time assure us that during his stay in the Church, blood continued to flow from the nostrils of the corpse. (*Regis utroque naris sanguine coepit manare et quamdiu filius in Ecclesiâ fuerat not cessavit.*—*Scripta rerum Francicarum*, xviii., 158.)

In the sixteenth century the same belief prevailed in Italy. Come de Medicis, Grand Duke of Tuscany, caused his son Garcias to be put to death, because his second son, the Cardinal de Medici, having been assassinated, the blood of the murdered man burst out at the sight of Garcias. Thus the false interpretation of a medical fact, true in itself, has cost the life of more than one innocent individual, and we cannot avoid surprise at finding that in the seventeenth century—the age more especially of literature, taste, and refinement—the same superstition should have existed in full force, and that the practice of appealing to the blood of a murdered individual was general.

Ranchin, Chancellor of the University of Montpellier, has written a very singular monograph upon this subject, entitled "Traité sur les causes de la cruentation des corps morts en presence des meurtriers." He enters upon his subject in the following manner:—"We look with pity and commiseration upon a naked

* Concluded from page 265.

corpse, pierced with wounds, and without any appearance of life; we see the judges, with certain ceremonies, present the individual suspected of being the murderer, and place him before the body, and we behold with delight the closed wounds re-open spontaneously, and pour forth blood, which cries for vengeance and demands justice. Is not this enough to astonish philosophers, physicians, and theologians." Ranchin, in treating of the subject, does so with the utmost solemnity and good faith, conducting his inquiry as minutely as did Don Calmet with regard to the vampires. He divides his work into twelve chapters, in which he endeavours to elucidate the following questions:—

1st. If the cruentation of dead bodies before their murderers be an absolute fact?

2nd. If the appearance of the phenomena to the judges and witnesses be sufficient to condemn the accused to death.

3rd. What are the ceremonies to be observed by the judges in presenting a suspected murderer to a dead body?

4th. What are the opinions of theologians upon this subject, as to whether this effusion of blood depend upon natural or supernatural causes?

5th. If demons and sorcerers may cause the effusion of blood?

6th. If the soul of the dead person is to be considered as returning and causing the effusion?

The remaining chapters are filled with inquiries relative to the power of spirits, the existence of sympathy or antipathy, or the agency of external causes in producing these effects. In fact, the whole subject is treated of in the most complete manner. The illustrious professor exhibits indeed a marvellous amount of erudition, and occasionally his good sense divests itself for a moment of the superstitious belief of the age; he, nevertheless, adopts the worst of theories, and rejects the only good one. Ranchin, in fact, concludes that the phenomena depend on the miraculous intervention of the Divinity, with a view to the detection of the culprit; in other cases he attributes them to the influence of demons, endeavouring to destroy innocent individuals. He thus entirely rejects the only true theory, that of a relic of vitality in the blood itself.

The phenomenon in question, however, affords its own explication, without having recourse to other causes than those of a vital character, since authentic facts prove, that such posthumous hæmorrhage may occur in cases of natural death, and even several days after the extinction of life.

During our short period of existence, our corporeal organs, linked as it were to the vital flame, become separated from it at death, only by effort. They retain always for a time, some few sparks of that divine fire which has animated and directed them during the curt period of time which they have traversed together. As wood remains still in a state of ignition after the flame has been extinguished, so with our internal organs, so with the heart, that centre of sanguification—the most noble, the most mysterious, whether physically or morally, of the centres which preside over the acts of

vitality. Thus, as the blood is the first formation in the embryo, and as in fact the first blood globule is the primordial rudiment, to which the principle of life is attached, so is it the last to die, and the most tenacious of preserving the last trace of existence. It was this characteristic that constituted one of the principal arguments of Harvey, who with justice speaks of the blood, as the first to live, the last to die; the "*primum vivens et ultimum moriens*."

To the preceding superstition, there succeeds one still more incredible, but equally capable of bearing witness to the truth of the assertion—that the "*life of the blood*" was an idea universally diffused among all classes, at the period alluded to. Vampirism, indeed, bears more than any other superstition upon the subject under consideration;—a moral epidemic, and one of the most degrading that the human race have to be ashamed of. It was at the commencement of the same eighteenth century, which was designated as the age of philosophy, that it prevailed in Hungary, Moravia, and even in France.

It is not very certain how the idea originated, that if one of two enemies were to die, he had the power of reappearing and recovering his life, by sucking the blood of the survivor. Of course the individual believing this superstition was liable to dreams, and malevolent spectres failed not to pursue and suck these imaginary victims, who were far more to be pitied than real invalids, and thus it was that a portion of Europe was for ten years frightened from its propriety. What could be more natural than the recital of a dream, more especially if extraordinary? and when repeated from mouth to mouth, with the usual additions, what more likely way of rendering the superstition general? It became so in fact, and the effect was so rapid that the exhausted dreamer died in a state of syncope, the victim of a diseased imagination.

To arrest this species of mental epidemic, it was thought better to humour it to a certain degree, and the magistrates of the period appear to have adopted the best means of putting a stop to it. They began by giving in to the popular belief on the subject, and pretended indeed, that they themselves believed in vampirism. To save the living, however, it was thought necessary to violate the sepulture of the dead. In doing so, the most rigorous exactitude was observed, and everything conducted in the most approved legal fashion; evidence was taken, witnesses were brought up on both sides, &c. &c., and if any imaginary evidence of vampirism was detected on the bodies of those, whom public opinion accused, their bodies were forthwith decapitated and burnt by the public executioner.

If, then, according to popular belief, the blood has had the power of resuscitating the dead;—if, in the eleventh book of the *Odyssey*, it restores to the shades of the departed the faculty of speech which they had lost at death;—if the shade of Tiresias pronounced its oracles only after drinking of that blood, which, while bubbling in its infernal receptacle, attracted around it the departed souls, thirsting for a victims blood;—if the fluid which flowed from the wound inflicted by

Jupiter upon Saturn should, in falling on the earth, have produced a race of giants;—if the blood of an outraged parent, should (as when Coelus was mutilated by Saturn) give origin to the Furies;—and if, lastly, the blood could give life to bodies hitherto unpossessed of it, and return it to those that had lost it, is it to be doubted, that a like belief may have led to its employment as a medicinal agent? And in truth such was the case.

The Romans for instance, when a gladiator was expiring, rushed to drink of his warm gushing blood, for the blood of the gladiator was looked upon as a specific in cases of epilepsy. Thus Celsus, (Lib. iii., cap. ii., sec. 10.) says:—"Quidem jugulasti gladiatoris calido sanguine poto, tali morbo se liberarunt." And according to Pliny, (book xxvj., chapt. 5.) The elephantiasis of the Romans could only be cured by baths mixed with human blood.

The belief in the remedial efficacy of the blood reappears during the reign of Louis XI. of France. It seems that old men were then in the habit of drinking it, with the view to the restoration of youthful vigour; and the king himself is reported to have drunk that of a child with the same motive; thus almost realising the fable of the vampires.

It is said that this singular custom was introduced by Jewish physicians, who, during the middle ages, were privileged to be the physicians of the whole of Europe. If this assertion be true, it is singular that such a practice should have originated among those whose religion strictly prohibited its employment, and who, while forbidden to use it as food, should have done so as a medicine.

But it has been sometimes thought necessary to diminish the vital energies; and at the time that this idea prevailed, it was as usual, carried out through the instrumentality of the blood, the inconsiderate expenditure of which, surpasses all that has been sarcastically said by Lesage and Beaumarchais, against the abuse of venesection.

There is a period in history, extending over about six centuries, during which the ridiculous expression, "minution," served to express a still more ridiculous custom. It was this:—Whether sick or well, no inhabitant of a cloister was exempt from the stroke of the lancet, and when once the vein had been opened, the blood was allowed to flow, until arrested by the superior of the cloister, that individual alone having the right to apply the compress. This custom had been so abused in some convents, that Louis IX. was under the necessity of imposing certain restrictions upon the inmates of the Hotel Dieu of Pontoise, by which they were prevented from being bled oftener than five times a year—viz., at Christmas, Lent, Easter, in the month of August, and on All Saints' day.

It is reported by certain historians, that up to so recent a period as the year 1788, there were some religious orders, amongst whom venesection constituted a species of discipline, to be undergone at least once a year. To render this as little irksome as possible, the day on which the operation was performed, partook of

the character of a festival. The community was divided into two parts, each of which, on a given day, underwent phlebotomy; during the three succeeding days, those who had undergone the process were considered exempt from all manual labour, and received double ration. After this, the superfluous blood having been removed, they resumed their occupations as usual, while the other half of the inmates were submitted to a similar ordeal.

Certainly the absurdity of this process is only equalled by the idea of Beaumarchais, informing the Hero of Seville that "the entire garrison will take aperient medicine on the morrow."

But, again, whenever the renewal of life, or at least its prolongation, has been a desideratum, the blood has been appealed to, as though it were the life itself. Hence arose the celebrated method of transfusion, described by Libavius, (a disciple of the school of Paracelsus,) 150 years previous to the disputes between France and England, relative to the priority of the discovery.

"Take (says Libavius) a man on the point of death, and one in full vigour, then, having two silver tubes, open the artery of the healthy individual, and introduce one of them, do the same by the sick man, and then cement the tubes in such a manner that the blood of the former shall flow into the arteries of the latter; the result will be, the disappearance of every infirmity, the source of life having been restored."

It is evident that at its origin, this process was looked upon as an assurance of immortality, since, to use the words of Libavius, "the source of vitality itself was appealed to." But the restoration of youthful vigour through the instrumentality of the blood is no new idea, it dates, indeed, from the age of fabulous history, from the same epoch from which date all the instinctive ideas of man, who, when first perceiving his own infirmities, would naturally wish to avert them. Did not Medea restore to youth Eson, father of Jason, and to avenge herself of Pelias, did she not cause him to be sacrificed by his daughters, after persuading them that his venerable blood might be replaced by that of vigorous youth.

This idea of appealing to the blood, in cases where some modification of vitality was the object sought after, was after all, a very natural one, inasmuch as in the popular belief of the day "the blood was the life." * * * * And truly the blood is as it were the vehiculum of our existence,—the inextinguishable source of strength,—the germ of growth,—the essentially organizing and regenerating fluid. And how should it be otherwise, since it is the mainspring of that power which penetrates, animates, and keeps in movement, the different portions of the human machine; which forms, arranges, develops, and even repairs them. And when transgressing the laws of health, our organs become a prey to disease, the blood has in reserve many a wonderful resource to obviate its effects; as though containing within itself an inexhaustible treasure of life and organization.

The blood was denominated by Borden "a species

of liquid flesh," an expression most happily chosen. To complete it, we may say that this marvellous fluid actually fashions the mould in which it circulates; and that Prometheus like, but superior to, the Prometheus of ancient story, it furnishes in itself the creative power. But the blood, and the blood alone, possesses this peculiar property—this singular privilege; art, however far advanced, can never, will never, achieve such a triumph, nor even approach it. Art will never create even an atom of gelatine, a drop of milk, of blood, or of bile. And those physicians who allow themselves to be blindly led by the mere results of chemistry, are, as it were, walking backwards. They ignore the most essential part of the phenomena of the blood, without which the blood is no more blood, than is the cold corpse the living man.

But the instinctive belief of which we have been speaking, could not long exist without being represented through the medium of language. Language in itself, is nothing more than a depository for the thoughts, ideas, and wishes of the mind. It is the reflector or mirror, in which they assume a visible, tangible form. The instinctive notions of the mind, have on all occasions greatly influenced manners, customs, and institutions;—whether civil, religious, or political; morals have been imbued with them, and every species of popular belief tinctured by them. From thence, advancing a step further, they have shown themselves in various forms of speech. Language in fact, preserves and reproduces them at every step; and it is a remarkable fact, that if we investigate the matter a little, we shall find that in the various dialects of the human race, the blood is used as synonymous, not only with the life, but also with every modification of which, whether organic or moral, it is susceptible. In fact, whatever modification we may wish to express, we shall find in various languages the word blood substituted for the word life. Thus the blood is said to be on *fire*, *frozen*, *curdled*, *appeased*, *shed*, &c. Indeed every physical or moral change of which life is susceptible, has been described under this denomination. In organic life it expresses the containing for the contained; the vehicle for the power of which it is the bearer. In the moral life, it indicates the sustaining principle of this latter, and becomes the living, visible, and appreciable symbol, of an existence that is in itself spiritual, invisible, and untangible. It is evident moreover, that as the word life, metaphorically expresses the notion of intelligence, the word blood, which is also in turn synonymous with life, should also, metaphorically, express the principle of intelligence, and hence the meaning of the word blood, in the tragedies of Seneca, where it is designated as possessing all those qualifications which might, with propriety, be attributed to the principles which guide the free will in the performance of various actions. Thus, the terms *magnanimous*, *abject*, *unjust*, *powerful*, *hostile*, &c., are applied to the blood by substitution, in the writings of the ancient tragedians; while similar terms are employed in the numerous proverbs, which in all ages have had the vitality of blood for their fundamental idea.

The public then, it is evident, are in possession of very important truths on almost every subject, even in relation to the science of man. Many a treatise has been written upon *popular errors*; a more interesting one might have for its subject, *popular truths*. Public opinions, when widely diffused, are always extremely worthy of attention; they generally conceal precious truths, modified, indeed, by the influence of time, but requiring only to be restored to their noble and primitive simplicity.

These truths pertain to the moral instinct of a people, and afford important food for meditation. Nature has exempted man from the necessity of seeking, through the instrumentality of reason, those rules which should regulate his conduct towards his fellow-creatures; these she teaches him by a species of inspiration, and by that internal satisfaction which results from their performance. She leads, indeed, the multitude by the impressions of a moral instinct, and by a vague and even unreflecting sense of truth; but to the philosopher only does she condescend to explain her motives. He, however, may seek and discover the intimate connection between popular belief, and those facts which form the ground-work of his own doctrines; and thus, while demonstrating such connection to those who are merely conscious of its existence, may confirm, by reflexion and inductive reasoning, that which to the many is but the impression of an instinct.

Cheltenham, June 1, 1852.

Provincial Medical & Surgical Journal.

WEDNESDAY, JUNE 23, 1852.

IN our recent remarks upon Dr. COWAN'S suggested alterations in the management of this journal, we candidly admitted, that although, as we have reason to know, it is conducted to the satisfaction of the great majority of those members whose interests and opinions it represents, there is considerable room for improvement. The question is—How is that improvement to be effected? Is the defect—admitting a want of perfection to be such—to be laid to the score of the Editors, or of the subscribers to the *Journal*—the Members of the Association generally? Now, as regards ourselves, we are far from wishing to assume more than is our due—nay, more, we have no objection if it will be agreeable to those who wish for a modification in the management, to avow that in some respects we are inferior to our metropolitan contemporaries. At the same time we must, in self defence, remind Dr. COWAN, that the positions of a London and a Provincial Editor are totally

different. Not only is our London *confrere* more immediately in the way of obtaining early information respecting the great medical bodies, whose movements are just now watched with unusual interest, but they are more *au fait* with the medical small talk, which some may think indispensable to the pages of a journal, as a sort of *chasse* to aid the digestion of the more solid intellectual food. It is not difficult, therefore, for him to surpass us in variety of matter for "Leaders" and in the "news" department. This is, however, we maintain, a secondary consideration in the conduct of a journal, for the opinion of an editor upon a given point is, after all, the opinion only of an individual, which may or may not have weight with his readers.

But while thus admitting that some circumstances favourable to the Editor of a London journal give him an advantage over us, we cannot forget other circumstances which must inevitably render our position a difficult one in comparison with his, even were we equally favourably situated in other respects, and which would equally attach to the Editor of this journal if conducted in London. This journal is not, as we have before observed, the speculation of a bookseller, who cares nothing as to what his Editor may write about, or how he writes, so long as a certain number of copies are sold weekly, but it is the organ of a body of nearly two thousand members, of many shades of opinion—medical, political, and religious. It might be predicated in such case, that no Editor or Editors could give universal satisfaction; utter what sentiments he may, he will be morally certain to impinge upon the prejudices of some. And so it has proved as we could readily show.

Dismissing, however, the difficulties which are in a manner inseparable from our Editorial labours, we would suggest that these labours form only a portion, and not the most important of the material of a medical journal. The main value of such a publication must depend upon the exertions of its contributors, and we must be allowed to urge on this point, that in proportion to numbers and talent of our constituency, we are not supported as we ought to be, by original contributions. Seldom, we regret to say, do we see the valued proceeds of Dr. COWAN's pen, which, together with others of a similar stamp, would go far to render the *Journal* what he and we also should wish to see it. There is assuredly

no lack of able writers in the ranks of the Association; on the contrary, it abounds with men inferior to none in intelligence and acquirements, medical and literary. Whatever prospect for the improvement of our journal may be entertained, this mode of enhancing its value will we trust not be overlooked, for without it all others will prove vain. If our subscribers will only put their shoulders to the wheel, and furnish us in greater abundance with the results of the enlarged experience and cultivated knowledge we know so many of them to possess, we shall have at once *the right mode* of improving this journal; and not improving it only, but of making it in scientific and practical interest, the equal of any in the kingdom.

Proceedings of Societies.

MIDLAND BRANCH.

THE first annual meeting of the MIDLAND BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION was held in the Exchange Hall, Nottingham, on Thursday, the 3rd of June. The attendance of members was large, besides whom were a few who were not associated with the Society. Among those present we perceived Dr. J. C. Williams, of Nottingham, the President-Elect; Dr. Bent, of Derby (the retiring President); A. Darby, Esq. (the Honorary Secretary), Dr. Hutchinson, Dr. Ransome, Dr. Gill, Dr. Slone, Dr. H. Payne, jun., B. Eddison, Esq., H. Taylor, Esq., J. E. Stanger, Esq., J. M. L. Marsh, Esq., Dr. Hynes, J. N. Thompson, Esq., Joseph Thompson, Esq., Joseph White, Esq., Nottingham; T. A. Burrows, Esq., Snetton, Notts; B. W. Brown, Esq., Wymeswold; — Eaton, Esq., Grantham; — Scott, Esq., Mansfield; Alfred Cooper, Esq., Leicester; Dr. Goode, Derby; Dr. Smythe, Bingham; T. Paget, Esq., Leicester; Dr. Shaw, Leicester; A. Greaves, Esq., S. H. Evans, Esq., D. Fox, Esq., Dr. Heygate, Dr. Harwood, T. Hamilton, Esq., S. W. Fearn, Esq., J. Jones, Esq., Derby; T. Cantrell, Esq., Wirksworth; — Ellans, Esq., Sandiacre; T. Browne, Esq., Castle Donnington; — Lynch, Esq., Manchester, &c.

The chair was taken precisely at three o'clock by Dr. Bent, of Derby, the retiring President, who said:— I cannot allow this occasion to pass without congratulating you on the prospect of having a gentleman to preside over you in the ensuing year so highly endowed, so well informed, and so excellently fitted for the office of President as my friend, Dr. Williams. I am sure you will concur with me when I express my belief that when his year has passed away, it shall have been found that he has conferred a distinguished honour upon the Midland Branch of the Provincial Medical and Surgical Association. (Applause.) It has been hinted to me

that I ought, before vacating this seat, to make something like an address. I do not concur in that opinion, for very many reasons. One leading reason is, perhaps, a very selfish one, and, therefore, I shall say nothing about it. I think, when we see by the paper that it is the intention of our future President to address you, and that there will be a report of the Secretary, which will take a retrospective view of the proceedings of this Branch of the Provincial Medical and Surgical Association, and likewise that there are several other papers to be read, you will feel with me that were I to say anything further I should be occupying your time most unnecessarily. There is a great deal in the notice paper to read that will supply you with a very copious intellectual banquet; and only a very short time will elapse before we shall have to adjourn to another banquet of a more animal and corporeal nature. (Laughter.) I beg, therefore, to vacate that chair, which I feel assured, gentlemen, will be so much better filled by my friend, Dr. Williams. (Applause.)

The President, on taking the chair, delivered the following introductory address, which was much applauded:—

Gentlemen,—In accepting the office of President of the Midland Branch of the Provincial Medical and Surgical Association for the ensuing year, I beg to thank you for the agreeable and flattering mark of your confidence. I am aware of the many imperfections with which I shall conduct your proceedings; but I am also aware that I shall receive from you every assistance and indulgent kindness. I was requested to deliver to you an address; but I cannot take one step in my duties without first paying, in my own name as well as in yours, our grateful thanks to your late President, Dr. Bent, who has given us the advantage of his deservedly high standing in the profession, as well as his position in social life. Dr. Bent came to our first meeting at Derby, and he assisted us greatly in the formation of this Branch. He accepted the office of President, and has presided over our meetings with firmness and dignity, as well as urbanity and courtesy. Had my own inclinations alone been consulted, we should have re-elected him President for another year. I believe Dr. Heygate, of Derby, first suggested the formation of a Midland Branch of the Provincial Medical and Surgical Association, to unite more closely together the practitioners of Derby, Leicester, Lincoln, and Nottingham. The meetings have been held at Derby, and attended by the most influential practitioners; our future meetings during the year will be here, and either Lincoln or Leicester chosen for next year.

I will now briefly explain to you the objects of our Association, for I find they are imperfectly known amongst us. Twenty years ago the scattered and disunited members of our profession in the provinces were scarcely personally known to each other, when Sir Charles Hastings, of Worcester, our President of the Council, first suggested an honourable combination and occasional mutual intercourse. He foresaw the great advantages to the profession, as well as to the public, of an Association of this kind; and for originating and maturing such a project we owe him a lasting debt of gratitude. His time, his talents, and untiring energies have ever been at the service of the Associa-

tion. It is well known that he possesses the *fortiter in re*, but he has always shewn to us that *suaviter in modo* which is becoming in all men, more especially in members of our profession, and always the characteristic of an educated gentleman. The objects of this institution, which Sir Charles Hastings founded, and still so ably supports, are—

"1st. Collection of useful information, whether speculative or practical, through original essays, or reports of provincial hospitals, infirmaries, or dispensaries, or of private practice.

"2nd. Increase of knowledge of the medical topography of England through statistical, meteorological, geological, and botanical inquiries.

"3rd. Investigations of the modifications of endemic and epidemic diseases in different situations, and at various periods, so as to trace, so far as the present imperfect state of the art will permit, their connection with peculiarities of soil or climate, or with the localities, habits, or occupations of the people.

"4th. Advancement of medico-legal science, through succinct reports of whatever cases may occur in provincial courts of judicature.

"5th. Maintenance of the honour and respectability of the profession generally in the provinces, by promoting friendly intercourse and free communication of its members, and by establishing among them the harmony and good feeling which ought ever to characterise a liberal profession."

The Association is managed by a President, chosen annually, a President of the Council, Secretaries, and Council. There is an annual meeting in some important town, the place of which is changed yearly. The Anniversary will be this year at Oxford, on the 21st and 22nd of July next. The subscription is one guinea per year; and for such subscription each member receives a copy of the journal of the Association, published every fortnight, and a copy of all the publications issued for the general use of the members of the Association. The members of the Association are at liberty to form district branches, and the expenses incurred by the district secretaries in conducting the proceedings of the district branches are to be defrayed in a definite proportion from the general fund. Thus, you perceive, there is no additional expense to individual members who join the district branch. There is also a Medical Benevolent Fund connected with the Association, and, as it were, springing out from it, supported by voluntary donations and subscriptions, and deserving every assistance and support. Those distinguished philanthropists in our Association, Messrs. Daniel, Newnham, and Propert, have so ably brought the subject of Medical Benevolent Funds and Colleges before the profession, that no one now doubts their great usefulness. Mr. Newnham eloquently says (*vide Provincial Medical and Surgical Journal*, March 3rd, 1852), "Wherever there is embarrassment, wherever sickness has deprived a family of their means of support, when death has left a household in destitution and helplessness, often starvation, wherever the sting of misery is to be assuaged, or the feeble efforts of penury to be encouraged or sustained, and finally, when the bed of death is to be softened, and the last hours of life to be irradiated by the bright ray of charity, there is the peculiar sphere of operation for the Medical

Benevolent Fund." Surely such objects are in themselves good, and we hope by our proceedings to enjoy the confidence of the public and the esteem of our profession. The papers read and the cases related at our meetings will be open to discussion and observation; by this mutual interchange the learning and knowledge of each individual become the property of the whole. The older practitioners test their own experience by the result of the experience of each other, and the younger ones gain confidence and knowledge by these practical observations and discussions, and impart to their more advanced colleagues the rapid discoveries in science, and the improvements in the practice of the schools.

Let us briefly consider one or two subjects which accord with the avowed objects of our Association. The natural advantages of Nottingham ought to make it one of the most healthy towns in England. Its sandy soil, its elevation, its pure springs, its beautiful river—"the silver Trent,"—affording its inhabitants an unlimited supply of water, all tend to its healthiness, to the prevention of disease, and to the prolongation of life. The mortality tables show it so, in the best parts of the town; but in other parts, back-to-back houses, overloaded cesspools, defective drainage, and imperfect ventilation, have so engendered and propagated disease, especially among children, that we now enjoy the unenviable notoriety of having very nearly the highest mortality in England. These kinds of places I have mentioned are the localities in all large towns where epidemic diseases find ready-made receptacles to receive and spread their contagious influence. In our insular position they come to us over the wide waste of waters mingling with the moaning night wind, and poisoning the first sweet breath of morning. Into these heated, crowded, badly-drained, and worse-ventilated habitations of our working classes, they come but to revel in a banquet of death. Their first victims are the helpless, the poor, the sickly children, delicate needle-women, and industrious artisans, who are compelled to live in these unfit dwellings, because better ones have not been provided for them. The poor are the first victims; but the blighting influence of epidemic diseases will not spare the opulent. It is wisely ordained that the health and the lives of the rich shall, in great measure, depend upon the provision they make for the comfort and health of the poor, neglect of these causing the pestilence to fall on their own dwellings. I am gratified to state, great efforts have lately been made by benevolent and philanthropic individuals, to improve the houses of the working people. The board of Guardians have done the best they could in their official position. The Town Council appointed an intelligent and efficient Sanitary Committee, whose labours have been most useful and important. The New Inclosure Bill gives us the opportunity of building more commodious and more healthy dwellings for working people. It has given us increasing grounds, beautiful walks, and a fine arboretum. These advantages will not be lost sight of by our shrewd and thoughtful population, and I feel satisfied Nottingham will soon take one of the highest places among the manufacturing towns of England, and I hope will also take the lowest place in the scale of mortality. Were I to pursue this subject further, I should trespass on the paper on the "Medical Topo-

graphy of Nottingham," which I know will be most ably explained to you by my friend Mr. Joseph White.

I will now briefly call your attention to the charitable medical institutions of this town. The General Hospital is the oldest, it has been established 70 years, it contains 120 beds, since its formation there have been 145,607 patients—37,971 in, 107,816 out. It is supported entirely by voluntary subscriptions and donations, and is very ably managed by a president, vice-president, and committee. The hospital has always maintained its place as one of the highest rank in the provinces. The use of chloroform was scarcely known to the profession ere its efficacy was tested at our hospital. Mr. J. White, the intelligent resident surgeon, has kindly furnished me with the following results:—Chloroform has been given to 367 patients. The average time of inhalation preceding insensibility five minutes and a half. The average time of perfect insensibility thirteen minutes. The longest time of perfect insensibility one hour and a quarter. The average quantity used for each case, two drachms and a half, and the largest quantity used for one case, one ounce and five drachms. In all these cases no unfavourable or fatal result has taken place. At St. Bartholomew's Hospital, there has lately been one fatal case worthy of notice, from the state of the blood.* The patient died from the effects of chloroform whilst preparing for an operation to be performed by Mr. Lloyd. The *post-mortem* appearances were as follows:—"The viscera were all healthy, the blood was fluid, and it remained without coagulation after its escape from the heart and vessels. It had also a brownish and purple hue much like that which is commonly observed in the spleen, none of it when thinly spread out, presented the ordinary dark, black, or crimson hue of venous blood." From this condition I would notice one important fact, that there are persons in all respects sound and healthy, upon whom chloroform absorbed in certain quantities into the circulating fluid acts as a poison, and may cause the rapid extinction of life. We should therefore never use it lightly or unnecessarily, and always with every due care and caution. Our General Lunatic Asylum has been established forty-one years, it now contains 240 patients—116 females and 124 males. The patients are partly private patients and partly paupers, and it is supported by the parish rates, the payment of patients, and charitable subscriptions. There is also a most admirable benevolent fund, which was established by the late lamented Dr. Blake, called the Lady Middleton Fund, from the munificent donation of her ladyship to it. It gives relief to the poor patients until they are enabled to obtain work. It has prevented the relapse of many a patient, and given maintenance and comfort to his home. This asylum was built when the treatment and management of the insane was conducted on very different principles to the enlightened and humane method of the present day. The building, therefore, ought not to be put in comparison to the new asylums, which are now springing up in almost every county, replete with every advantage for medical treatment, classification, and management. A large and rapidly-increasing population has grown up around it which has now made its locality far less

* *Medical Times and Gazette*, April 8th, 1852.

favourable a situation than when it was built; but to obviate this disadvantage several acres of land have just been purchased to add to its means of employment and its recreation-walks. The medical and moral treatment of our patients has long been on what is popularly known as the non-restraint system; a misnomer I think if we take the word in its literal meaning, viz., that there is no restraint whatever in the management of the insane; but correct if we and the public understand by it, non-personal mechanical restraint, that is, that fetters and restraint chairs are never applied to the persons of the unhappy inmates of our asylums. This humane method was first pointed out in France, by the great Pinel, and afterwards the justly celebrated Esquirol directed public attention to it throughout civilized Europe. One of the most distinguished members of this Association, my valuable and old friend Dr. Conolly, is identified in England with its benevolence and success. Hanwell, under his able management has become an example to all the asylums in the world. We have also in Nottingham an important and well-managed dispensary. It was established in 1831, and is supported by donations and voluntary subscriptions. Since its establishment 73,448 patients have been treated by its medical officers. It possesses one great advantage to the poor who are too ill to leave their own dwellings, viz., that the medical officers of the institution will visit the patients so afflicted in their own homes. It is a most useful institution and does a great amount of good. The Midland Institution for the Blind must not be omitted. This is one of the new institutions of the town of Nottingham, as well as of the midland counties, and well worthy of all the support it has already received. "Its first object shall be the instruction and employment of the blind of both sexes—some as boarders, others as day pupils. The instruction to include the daily reading of the Holy Scriptures, and all the employments to be of a useful character." It was commenced about ten years since, by a few benevolent and Christian individuals, who made this effort to rescue the poor, ignorant, and degraded blind from their destitution and misery. In no town in England is such an institution more needed, and in no other town could its situation have been more properly fixed. The nature of the employment in trades of hosiery and lace induces great weakness and loss of sight in the working people. Some idea may be formed of the extent of the ophthalmic diseases when I state that, in 1846, I made a report to the factory commissioners of my own attendance upon above 16,000 ophthalmic cases. I feel a great interest in the success of this institution, which can do so great an amount of good; and I would suggest that we engraft upon it an Ophthalmic Hospital. It could be done easily and at comparatively little expense, and would be a great boon to the working people of Nottingham. Such is a brief notice of our principal medical charities. Some few years since his Grace the late Duke of Newcastle most munificently gave to us £500, to form a medical school in the town of Nottingham. I deeply regret it was not successfully carried out. It has made us behind other towns in England, which we feel we ought not to be, and need not be, but we are not the less grateful to our munificent patron.

The liberal offer of Mr. Lawson is well known to us all in reference to the establishment of an observatory. We hope it will be responded to so freely as to secure to us the advantage of so scientific and highly important an institution. The paths of science and literature have not been left uncultivated by the medical men of Nottingham. They have contributed their share to the advancement of both, as well as to the improvement of the practice of our profession. I should detain you too long were I to enter into an individual detail, but I cannot omit the name of Dr. M. Hall, who, being a native of this immediate neighbourhood, and having been a practitioner amongst us, makes us most justly proud of a contemporary whose European celebrity gives a lustre to our town, as well as to our profession. I need scarcely tell you that a numerous class of sympathetic actions receive their explanation from Dr. Marshall Hall's beautiful development of the reflex function. It is now fully established that the spinal marrow constitutes a centre of nervous influence perfectly independent of the brain. Irritation of the sentient extremity of a nerve may be propagated backwards to the spinal marrow, where it implicates the motor roots, and from these latter it is reflected on the various parts to which the motor filaments are distributed. This simple and elegant theory explains many of the effects of injuries to the sentient nerves, and gives a clue to an immense number of acts which thus become morbidly associated with our sensations, and which, prior to Dr. Marshall Hall's discoveries, were completely unintelligible. He has presented to us also other facts and observations of great importance, to which I could scarcely do justice if I devoted to them the whole of my address. We cannot all aim at brilliant discoveries nor lofty distinctions, but we may all, by sincere, laborious, and truthful devotion to the paths of science, and to the honourable exercise of our profession, contribute to the cause of improvement and of human happiness. We know indeed—"Nil sine magno vita labore dedit mortalibus"—but that labour is amply repaid to us by our personal advantages and increased happiness. The public labour of the last year was the Great Exhibition, an event which cannot as yet be passed over in silence, which can scarcely be mentioned out of place in Nottingham, whose mayor, and some of whose principal manufacturers were so successfully and honourably identified with it, and whose machinery and manufactures took so prominent a place within its crystal walls. It is, however, interesting to us medical men, on many accounts, especially in reference to the health and happiness of so great a number of our fellow creatures. In contemplating its glories and its wonders, if we fall back upon our early studies, in the writings of scholars and historians, we are forcibly struck by comparison with the rapid and gigantic strides of civilization. We are not yet quite certain what influence this Exhibition may have had upon human health and disease. It was feared by many that the collection in London of so many extra thousands of persons of all ages and of all sorts of bodily condition, from such varied localities, would be the means of bringing, engendering, and propagating disease. I am not aware that has been the fact, nor that either the aggregate health of the people has been deteriorated, or the

mortality increased by the occasion. Doubtless many individuals were made ill, by hard work, irregular hours, and by great excitement. In many cases the nervous system suffered severely with general debility and mutual disturbance, a prolonged depression having succeeded to the excitement. I noticed also cases of low fever, with tympanitis, and very slight peritonitis, occurring in persons who had made hasty and fatiguing visits to the Exhibition. I believe most of us in this neighbourhood noticed, in the autumn and early winter, a great number of cases of eruptive diseases, such as boils, blotches, and carbuncles. These were attended by a slight disturbance of the digestive organs, and considerable debility, and were so numerous as almost to be considered epidemic. I have thought that this peculiar state of the constitution might have been created in some cases by the inhalation of the mixed impurities of the atmosphere of the Exhibition. I know every care was taken for good ventilation, and with as much success as possible, but there must have been day by day an unhealthy condition of the atmosphere produced by the expiration from the lungs, and the exhalation from the bodies of so many thousand persons of all sorts of constitutions and countries, and so many of whom, without doubt, had neither normal skins nor lungs. Would not the blood receive these impurities from the atmosphere, and when carried into the system, would not the *vis medicatrix nature* endeavour to throw them off by the skin? It may be so, or it may not, for great as are the discoveries in chemistry, we have not yet been able to detect the precise manner in which the blood is acted upon by malarious influences, or to detect the poison itself in the blood.

Organic chemistry, which is the growth of the present century, has unfolded to us most important facts in physiology and pathology, the chemistry of respiration, and of the healthy and diseased conditions of the fluids and solids. The microscope is to us a new method of discovery. It has extended to us the field of vision far beyond its natural limits. It has enabled us to follow the most minute ramification of structure from the beginning to the end, to examine the fluids which form the solids of the body, distinguishing health from disease, showing us what is malignant and what non-malignant formation, and pointing out to us the nature of those changes which have taken place in the blood, in the urine, and in all morbid discharges. Thus not only has physiology received an impulse, but pathology also has made rapid advances. The observations of the microscope, and the results of organic chemistry, are yet in their infancy; there is no limit to their progress, for finality in knowledge of the things of this world is inconsistent with the spirit of man; and when we trace the ultimate formation of all organized bodies in nature, whether animal or vegetable, we are involuntarily and happily taken from Nature up to Nature's God, for "God, and God alone, is king of nature, his voice the fountain was from whence it sprang." Among many distinguished names and highly important observations by the microscope, and in organic chemistry, one cannot but mention that Schleiden and Schwann first developed the beautiful cell-theory, viz., (*vide* Mr. Bishop's address to the

Med. Chirg. Society, March 15, 1852,) "The Ultimate Development of Cells into all the Tissues of Vegetables and Animals, and the perfect Analogy between the Animal and Vegetable Cell." There are now many able investigators and discoverers in this new field of science, seeking carefully and patiently for its truths, and this is the characteristic of the laborious studies of all honourable and right-minded medical men.
